**Abstract:** The present study aimed to investigate for a possible hepatoprotective activity of *Raphanus sativus* against carbon tetrachloride induced hepatotoxicity beside its toxicity and phytochemistry of the plant. Thirty albino rats were divided into 6 groups. The first served as a control, the second was injected with CCl₄ and the four other groups were injected with CCl₄ and treated orally and simultaneously with either methanolic or water extract at doses of 200 and 400 mg kg⁻¹ (b wt.). The animals were sacrificed after 10 days. The same doses were tested for toxicity. The phytochemical tests revealed presence of terpenes, alkaloids, flavanoids, tannins, saponin and coumarins but negative for cyanoetric glycosides and antiruquinone glycosides. Biochemical results showed that CCl₄ induced hepatotoxicity which was reduced by the use of the plant as indicated by inhibition of the increased serum AST, ALT and ALP activities and bilirubin concentration beside histopathological changes. Toxicity study indicated that *Raphanus sativus* had no adverse effect on livers.

**Key words:** *Raphanus sativus*, carbon tetrachloride, hepatoprotective

**INTRODUCTION**

Liver damage remains one of the serious health problems. Numerous medicinal plants and their formulations are used in ethno-medical practices. *In vivo* and *in vitro* evaluation models have been developed for the ability of the plants to prevent or cure liver toxicity in laboratory animals induced by various hepatotoxins (Evans, 2002). Clinical research has confirmed the efficacy of several plants in the treatment of liver diseases (Laper, 1998).

*Raphanus sativus*, some times known as Radish or Alfigel belong, to the family Cruciferae. It is widely used to compact bacterial and viral infections, inflammation and cancer (Fant et al., 1998; Terras et al., 1993). The ethnomedicinal information of the plant describes the use of aqueous extract to have antiurolithic activity in rats (Vargas et al., 1999).

Kirtikar and Basu (1987) reported the use of the plant as arthritimetic and in diseases of heart. Ethanolic and aqueous extract have shown to possess hepatoprotective effect on rabbits (Zaman and Ahmad, 2004).

The present study was carried out to confirm the Sudanese folkloric use of *Raphanus sativus* as a hepatoprotective agent.

**MATERIALS AND METHODS**

**Preparation of Plant Extract**

*Raphanus sativus* seed was obtained from Omdurman General Market, Sudan and identified at Medicinal and Aromatic Plants Research Institute, National Centre for Research, Khartoum in 2005.
The plant seeds were dried and extracted according to Harborne (1976) method. For aqueous extract the seeds were soaked in water for 2 h and filtered. The filtrate was frozen, dried till use. In methanolic extract 60 g granulated seeds were packed in a soxhlet apparatus and 100 mL chloroform was added to separate lipid and terpenoids, then unpacked and left to dry and repacked again with methanol to get the polar constituent.

Phytochemical screening of the plant was performed for sterols, triterpenes, alkaloids, flavonoids, tannins, saponins, cyanogenic glycosides, anthraquinone glycoside and coumarins. Ten grams of the powder plant kernel was refluxed with 100 mL of 80% ethanol for 4 h, cooled and filtered. The filtrate was screened using method of Harborne (1976).

**Animals**

Wister albino rats of both sexes were used. They were kept in cages and housed in standard environmental conditions of temperature, humidity and light. The rats were left for seven days adaptation and supplied with standard diet and water *ad libitum*.

**Experimental Design**

Two experiments were performed, one to study the hepatoprotective activity of the plant against carbon tetrachloride-induced liver damage in rats using water and methanolic extracts and the other about toxicity of the plant.

In hepatoprotective experiment thirty rats were used. They were divided randomly into 6 groups, 5 rats each and injected intra-peritoneally daily for 10 days. One group served as control and was injected with paraffin oil at a dose of 0.2 mL kg⁻¹ b.wt. Liver damage was produced in the other 5 groups by injection of carbon tetrachloride (CCL₄), which was mixed with 9th volume of liquid paraffin oil at a rate of 0.2 mL kg⁻¹ b.wt. Four groups out of these 5 groups received either methanolic or water extract of the plant at a dose of 200 and 400 mg kg⁻¹ b.wt.

For toxicological study twelve rats were divided randomly into three groups, four rats in each. One group served as control. The other two groups received daily, for 21 days, methanolic extract orally at dose 200 and 400 mg kg⁻¹ b.wt.

Blood samples were collected from the orbital plexus using halothane as an anesthetic (Waynforth, 1980). Blood was collected either on EDTA for haematology or in centrifuge tube to separate serum. Haematological studies measured according to Schalm (1965). Sera were analyzed for activities of serum tansaminases (Asparate aminotransferase and alanine aminotransferase) according to Reitmam and Frankel (1957) and alkaline phosphatase (ALP) according to Chemio method (1972). Total bilirubin concentration was measured as described by Jendrassik and Grof (1938).

Animals were necropsied after 10 and 21 days in the hepatoprotective and toxicological experiments respectively. Specimens from the liver, heart, kidney, lung and pancreas were collected immediately after slaughter, fixed in 10% formalin embedded in paraffin wax, sectioned at 5 μm and stained with hematoxylin and eosin (Drury and Wallington, 1980).

**Statistical Analysis**

Data were analyzed using the student t-test according to procedures described by Mendenhall (1971).

**RESULTS**

Phytochemical screening showed that *Raphanus sativus* was positive for triterpenes, alkaloids, flavonoids, saponins and coumarins but negative for cyanogenic glycosides and anthraquinone glycosides.
There were no clinical signs observed in the controls and those received either methanolic or water extracts. However rats received CCl₄ exhibited depression, loss of appetite and reduced body weight.

At necropsy the control group showed no pathological changes, but in group which received CCl₄, the liver was severely pale and hemorrhages beside congestion of the lungs and hearts. In the groups received methanolic extract or Raphanus sativus there was moderate paleness of the liver. On the other hand livers of rats received 200 mg kg⁻¹ b.wt. water extract were slightly pale with areas of congestion and congestion of the lungs. Livers of rats received 400 mg kg⁻¹ b.wt. water extract were slightly congested.

In group which received CCl₄ there was a significant transient decrease (p≤0.05) in the Hb concentration at day 5 and a significant decrease (p≤0.05) in the values of PCV at day 10. However in group received methanolic extract at a dose of 200 and 400 mg kg⁻¹, there was no significant changes in blood pictures. The groups of animals received water extract exhibited no change in hemathological values (Table 1).

In group received CCl₄, there were significant increase (p≤0.05) in the levels of AST and ALT at days 5 and 10. ALP and bilirubin concentration was significantly increased (p≤0.05) at day 10. The values of AST was not increased significantly in groups received 200 and 400 mg kg⁻¹ b.wt. methanolic extract (Table 2).

Nevertheless there was significant increase (p≤0.05) in the levels of ALT at day 5 and 10 in groups received methanolic extract but these values were lowered at day 10. ALP and the bilirubin levels were unchanged.

In groups received water extract there were significant increase in the activities of AST at day 5 but ALT and ALP at day 5 and 10. The bilirubin concentration was unaffected in both groups.

There were no pathological changes seen in the control groups which had been injected with CCl₄. Increased vacuolation of hepatocytes, congestion of central vein, necrosis and inflammatory infiltration

Fig. 1: Liver of animal received CCl₄. Notice the degree of vacuolation and haemorrhage. H and Ex (200x0.96)

Fig. 2: Liver of animal treated with CCl₄ and 400 mg kg⁻¹ methanolic extract of Raphanus sativus. Notice the degree of vacuolation Haemorrhage. H and Ex (200x0.96)

of lymphocytes beside haemorrhage were evident in the group received CCl₄ (Fig. 1). In group treated with 200 mg kg⁻¹ b.wt. methanolic extract the liver showed moderate vacuolation and congestion. In group treated with 400 mg kg⁻¹ b.wt. methanolic extract, the liver showed mild vacuolation (Fig. 2).

In the group which had been treated with 200 mg kg⁻¹ b.wt. water extract the liver showed vacuolation and congestion (Fig. 3), while the liver in the group which had been treated with 400 mg kg⁻¹ b.wt. water extract showed mild vacuolation.

In toxicity experiment there were no clinical signs observed in the experimental rats. However, there was an increase in the body weight in group received the methanolic extract of Raphanus sativus. The livers of the control group were normal but in the group received 200 and 400 mg kg⁻¹ b.wt. mild congestion in the liver was evident.

There were no significant changes in the hematological values between the groups. Also there were no significant changes in the activities of AST, ALT and ALP and bilirubin concentration.

However, histologically the liver showed slight congestion and dilation of the sinusoids in groups received Raphanus sativus (Fig. 4).
DISCUSSION

The results of the present study indicate that *Raphanus sativus* constitutes flavonoids saponins, alkaloids and coumarins. These findings were similar to those reported by Tawfik *et al.* (1978) but contrary to his finding cyscanogcyosite were absent. This may be due to the parts of the plants used as he used fruits beside seeds. However, Songsak and Lockwood (2002) reported presence of sulfaphene sulfaphane, glucodeldroeucin and gluconapin.

The present study demonstrated that clinical signs such as nervousness and weight loss were associated with administration of CCl₄. This might be attributed to the liver damage caused by CCl₄. These symptoms were masked by concurrent administration of the extract of *Raphanus sativus*.

CCl₄ has a transient effect on haemoglobin concentration which was counteracted by administration of *Raphanus sativus* since this reduction was unapparent. These results might indicate
that *Raphanus sativus* is free of active constituents that could have a haemolytic or inhibitory effect on blood synthesis (Onyeiili et al., 1998). Experimental liver damage was induced in rats by administration of CCl₄, one of the most potent commonly used hepatotoxicity. CCl₄ is biotransformed under the action of cytochrome P450 into trichloro-phenyl radical. This leads to the formation of lipid peroxides which play a role in its hepatotoxicity (Edwards et al., 1993).

In the present study, there were increased serum enzymes activities (AST, ALT and ALP) and concentration of bilirubin in rats treated with CCl₄ that might support the results obtained by Dobbs et al. (2003). This increase in serum enzymes activities were lowered when the plant extract was administered. Some plants have a hepatoprotective activity due to presence of antioxidants (Takeoka and Dao, 2003; DeFeudis et al., 2003). However, the phytochemical analysis of the plant revealed the presence of antioxidants such as flavonoids and saponins. The plant may interfere with free radical formation and its constituents might be responsible for the observed protective role against liver damage; hence its a beneficial action against liver damage induced by CCl₄.

However, the mediated suppression of the increased activities of serum AST, ALT and ALP and concentration of bilirubin by *Raphanus sativus* extracts has probably given protection against CCl₄-induced liver injury as supported by the histopathological findings. Moreover it also provided evidence for the plant hepatoprotective effect as the hepatic cells were undergoing an accelerated regeneration.

Tests for the toxicity of the extracts using the biochemical analysis for liver functions indicated that they were safe. The parameters used to test these functions in treated animals did not differ significantly from those of control animals.

In conclusion, *Raphanus sativus* extract result in a decrease in liver enzymes activities hence it could be a useful and safe agent to act as hepatoprotective. Further work to clarify its mode of action should be investigated.
