Department of Crop Science and Production, Botswana College of Agriculture, Private Bag 0027, Gaborone

**Abstract:** *Cassia abbreviata* commonly known, as Monepenepe in Botswana is a widespread shrub or medium sized tree or shrub belonging to the Caesalpinaceae family. In Africa it grows from Somalia to South Africa. It is important medicine plant utilized by people living in rural and urban areas where it grows. The bark and roots of the plant have medicinal properties that treat different ailments in Botswana and other countries where it grows. Too much cutting of the bark and root digging for medicinal uses has left many trees dead in Botswana. It is therefore recommended that removal of the bark for medicine should be in small pieces and not around the trunk (ring barking) if the tree is to be preserved. This study reviews the characteristics and medicinal uses of *Cassia abbreviata*.

**Key words:** *Cassia abbreviata*, medicinal, bark, roots, Africa

**INTRODUCTION**

Farmers extract a variety of non-timber forest products from the forest to consume or sale to generate income. These products include foods, fodder, medicine, spices, dyes, construction materials, fuel wood and utensils. Non-timber forest products are important for food security, health, social and economic welfare of rural communities. Non-timber forest products are also useful as insect detergents, fumigants and cosmetics.

The use of plants containing beneficial and medicinal properties have been known and used by man for many centuries. Medicinal plants, which constitute a segment of the flora, provide raw material for use in all the indigenous systems of medicine in Botswana.

Botswana is endowed with a variety of medicinal plants which grow wild despite the erratic rains. There are several important medicinal plants that are widely harvested and utilised by villagers in Botswana. *Cassia abbreviata* commonly called Monepenepe is one of common used medicinal plants in Botswana.

**Distribution:** *Cassia abbreviata* is wide spread in the tropics. In Africa it is found in dry thorn bush and woodlands from Somalia to South Africa at altitude of between 220 and 1520 m above sea level. It is found growing mostly in open woodland and wooded grassland, along rivers on hillsides and frequently associated with termite mounds. In Botswana it grows mostly in the north-east on termite mounds and in all kinds of woodland.

**Plant description:** *Cassia abbreviata* is a shrub or small to medium sized tree belonging to the Caesalpinaceae family. It is deciduous with a neat rounded crown, growing to a height of 3 to 10 m (Fig. 1a) and rarely reaches 15 m. The trunk is straight and the bark is rough, grey-brown, fissured and flaking. The bark is subdivided into broad prominent ridges.

The leaves are evenly compound with 5-12 pair leaflets per leaf (Fig. 1b). The leaflets are medium-large, oblong, thin and marginally entire. The leaves are green when new in early autumn and less striking as they mature (Fig. 1b). Flowers are pea-like, single, yellow and clustered in masses at the end of the branches. They appear at the same time with new leaves or just before leaves. The masses of flowers make a striking display and last for 4 to 6 weeks. Flowers appear from September to October and fruits from December to April.

The fruits are long up to 80 cm thin and cylindrical (Fig. 1b). The pods ripen nearly a year after flowering. They remain on the tree for long periods and deliquesce on the tree after seeds are mature (Fig. 1c). When the pod is dry seeds can be shaken out and the pod breaks up. The wood is fairly heavy (air-dry 900 kg m⁻³) hard and coarse in texture. The wood has pale brown sapwood and dark brown coarse-grained heartwood with pale blotches. The wood works easily, however the living wood is damaged by borers.

**Economic uses of C. abbreviata:** The tree has some important economic and medicinal uses appreciated by people living in rural and urban areas of Botswana.

**Medicinal uses:** The tree provides medicine, which treat many ailments\(^5\,\text{11}\). Both the bark and roots are used for medicinal purposes in Botswana. The bark is used to treat ailments such as headaches, diarrhoea, constipation and skin diseases. Powdered bark is used for dressing ulcers. A decoction of stem bark is used as a malaria remedy\(^5\,\text{12}\). The stem bark contains histamine or chemically related substance responsible for lowering high blood pressure\(^5\,\text{13}\). The bark is extracted by boiling with cattle urine and water and the extract is used as a purgative\(^5\,\text{14}\). The decoction of the roots is used against fever of gonorrhoea, pneumonia, chest pains, uterine pains and stomach troubles\(^5\,\text{7}\). The roots are also taken orally for suspected syphilis\(^9\). A warmed-up cold infusion of the root is held in the mouth for toothache\(^5\). The fluid extracts of the root has proved to be cardiotonic, diuretic and diaphoretic in pharmacological experiments\(^5\,\text{13}\). Extracts from roots and bark are used to treat bilharzias\(^7\) and black-water fever\(^11\). A commercial extract has been marketed for treating black water fever. Smoke from burning twigs is inhaled to cure headaches\(^5\,\text{7}\).

**Other uses:** The young branches and leaves are eaten by elephants, giraffe and kudu\(^5\,\text{10}\). Crushed leaves are believed to drive snakes from homes\(^3\). Monkeys and baboons eat pods\(^9\) and the seeds by brown-headed parrots\(^9\). The seeds are also sucked as tonic\(^6\,\text{7}\). Local people believe that eating meat cooked over the bark of
C. abbriviata result in successful hunting. In warmer
C. abbriviata is a good ornamental tree[5,7,10]. The tree has
been planted along driveways creating a bright avenue
during the flowering season[9]. The wood of Cassia
abbriviata is used as firewood[4-5]. The tree produces
good timber for furniture and joinery[3,9].

Propagation and management: The species can be
propagated from seedlings in the nursery (Fig. 1d) and
wildlings[4,5]. Cassia abbriviata has many seeds
(15,000 seeds kg-1)[9]. Germination of fresh seeds is good
and fast without any pre-treatment[5,7]. In Botswana seeds
have been soaked in water overnight and sown the
following day in a mixture of river sand and leaf mould or
compost. Fresh seeds are able to germinate after 10 days
although older seeds might take a long time to germinate.
It is difficult to find viable ripe seeds in the wild as they
are normally infested by parasites. Fresh seeds can be
stored for a long time kept dry and free from insects[9].
C. abbriviata develops a long taproot from quite early.
The growth rate is about 70 cm per year[9,10]. The tree is
drought resistant[7] however, young trees are susceptible
to frost damage[2,3,10].

Performance in an agroforestry system: The species has
not been introduced in any formal agroforestry system.
However, wildlife such as elephants, kudu and giraffe
eagerly feeds on young branches, twigs and leaves.
Monkeys and baboons eat the pods and brown-headed
parrots eat seeds. The tree provides bees with forage
during its flowering season.

CONCLUSIONS AND RECOMMENDATION

It has been observed that too much cutting of the
bark and root digging for medicinal uses (Fig. 1e) has left
many trees dead in Botswana and the tree may become
extinct. Removal of the bark should be in small pieces
and not around the trunk (ring barking) if the tree is
to be preserved. People should be encouraged to
plant few trees in the homesteads for their uses
as a way of reducing pressure on trees growing in
the wild.
