Abstract: The influence of age on serum biochemical parameters (AST, GGT, urea, uric acid, urea/uric acid ratio, total proteins, albumin, globulins and A/G ratio) was investigated in juvenile turkeys. Statistical comparisons were made for differences in values among different ages, from 76-148 day-old turkeys. Significant variations were observed in the analyses in relation to age of the birds for urea, AST and total proteins. This study also aimed to determine serum biochemical values for turkeys.

Key words: Turkeys, Meleagris gallopavo, serum biochemistry

INTRODUCTION
The Bronze turkey (Meleagris gallopavo, Linnaeus, 1758) is a breed of domestic turkey. They are the product of crossing domestic turkeys brought from Europe by colonists with the wild turkey, created in the 18th century. They are selected for breeding stock in many countries to produce high nutritive meat, feathers and for breeding flocks (Brant, 1998).

Serum biochemical analyses may be used to detect organ dysfunction and disease and reports of bird blood ranges rarely state age. Our objective was to determine the variation in blood chemistry values (total protein, albumin, globulins, albumin/globulin ratio, urea, uric acid, urea/uric acid ratio, Aspartate Aminotransferase (AST) and Gama Glutamyltransferase (GGT) arising from differences among ages in juvenile turkeys. An additional objective was to establish reference values for the species.

MATERIALS AND METHODS
Turkeys were allocated in experimental floor-pen housed, receiving water and feed ad libitum. The feed was formulated with corn and soybean for growing birds according to NRC (1994) recommendations.

Blood samples were collected from the ulnar superficial vein of 70 Bronze Turkeys (26 turkeys of 76 days of age, 13 turkeys of 118 days of age, 20 turkeys of 133 days of age and 11 turkeys of 148 days of age). Aliquots of each blood sample were transferred immediately to a 10-mL plain glass tube containing no anticoagulant for serum chemistry analyses. The serum chemistry parameters (uric acid, urea, total proteins, albumin, AST and GGT) were determined with a semi-automated spectrophotometer chemistry analyzer (LabQuest®, Labtest®). The globulin value was determined by difference between total protein and albumin. The ratio albumin/globulin was calculated and the ratio urea/uric acid was also calculated: urea (mmol/L) x 1000/uric acid (μmol/L) (Lumeij, 2000). The control of the chemical analysis was made using Qualitrol-N. The data were analyzed by ANOVA and those with statistical differences were submitted to the Tukey’s test at 0.05%, using Statview® (version 5.0).

RESULTS AND DISCUSSION
Serum biochemical values for turkeys at different ages are shown in Tables 1, 2 and 3. There were no statistical differences in the serum biochemical values (albumin, globulins, A/G ratio, GGT, uric acid and urea/uric acid ratio) between ages. Bounos et al. (2000) reported similar results for albumin, uric acid and AST in juvenile wild turkeys and Scott et al. (1933) also reported similar results for uric acid concentrations in 7 month-old Bronze turkeys.

Significant differences in total serum protein values were found among different ages of juvenile turkeys (Table 1). In this study, total protein values for 76 day-old turkeys were lower than the values for 118, 133 and 148 day-old turkeys. These values, for 76 day-old turkeys, were also lower than values reported for 4 month-old wild juvenile turkeys.
There was evidence for age-related differences in urea concentrations (Table 3). Older turkeys (148 day-old) had lower values than 76, 118 and 133 day-old turkeys. Urea is considered to have limited diagnostic value in the detection of renal disease in birds compared to that of uric acid, but in this study there was no significant difference among uric acid values among different ages. Although according to Campbell (2004) the blood uric acid concentration is influenced by species, age, diet, juvenile birds tend to have lower blood uric acid values than adults. In a different way, it seems reasonable to speculate that age influences the concentration of urea in turkeys. The ratio of serum urea and uric acid can be used to differentiate prerenal and renal causes of azotemia (Lumiei, 2000). This ratio was calculated in this study because according to Lierz (2003) normal ratios must be established for each bird species and there is no previous report on urea/uric acid ratio available for turkeys.

**Conclusion**: Many of the evaluated parameters differed significantly (AST, urea and total serum protein) among ages. The effect of age should therefore be considered to avoid undesirable sources of variation and thus misjudgment for some blood parameters. The clinical chemistry results of Bronze juvenile turkeys obtained in this study can be considered as representative values for this species.
