Abstract: Type 2 diabetes mellitus is a chronic, progressive illness that causes considerable morbidity and premature mortality. More people are still having tendency to use herbal or alternative remedies. Zinc is a trace mineral which may be effective in diabetic patients. We evaluated the effect of zinc sulfate on biochemical markers of type 2 diabetic patients. In a randomized, controlled trial on diabetic subjects, forty patients received randomly either 660mg zinc sulfate or placebo for six weeks. Body Mass Index, Blood Pressure, Fasting Blood Sugar, 2-h postprandial glucose, Glycated hemoglobin, Triglyceride, cholesterol, low - density lipoproteins, high - density lipoproteins were checked before and six weeks after beginning of the study. HbA1C, BMI and Blood Pressure were measured after 12 weeks to evaluate the long term effect of drugs. The mean age of patients was 52.87±8.80. level of FBS, 2HPP, HbA1C decreased after six week treatment with zinc sulfate but it was not statistically significant. Due to zinc sulfate administration, significant decrease occurred in TG (P=0.005), chol (p=0.02), LDL (0.01) and systolic blood pressure (p=0.02). HDL was increased but it was not significant. No statistically significant differences were found prior to and after zinc treatment in BMI and diastolic blood pressure. After 12 weeks, there was a significant decrease in HbA1C (P=0.04) with zinc sulfate consumption. Zinc sulfate consumption in addition to other nutritional and pharmacological treatments in type 2 diabetic patients could be effective in lipid profile.

Key words: Zinc sulfate, Type 2 diabetes mellitus, lipid profile

Introduction: Type 2 diabetes mellitus is a polygenic disorder resulting from interaction of both hereditary and environmental factors (Jinlin et al., 2007). It is a chronic, progressive illness that causes considerable morbidity and premature mortality (Kleefstra et al., 2007, Amos et al., 1997). The worldwide prevalence of type 2 diabetes is high and is increasing steadily (King et al., 1998). Approximately, 150 million people worldwide are affected by type 2 diabetes mellitus and this figure is expected to double in the next 20 years (Freeman and Cox, 2006). Prevalence of type 2 diabetes is 13.8% in Yazd province, Iran (Afkhami-Ardekan et al., 2001). Type 2 diabetes is associated with the increased risk of microvascular and macro vascular complications (Nazimek-Siewniak et al., 2002). Zinc is known to be an essential trace mineral which is necessary for health and growth and is also essential for the function and activity of over 200 metalloenzymes (Chen et al., 1991). The ability of zinc to retard oxidative processes has been recognized for many years (Powell, 2000). Zinc is an essential mineral that is required for various cellular functions. Its abnormal metabolism is related to certain disorders such as diabetic complications (Song et al., 2005).

Abnormal zinc and lipid plasma levels occur more frequently in metabolically uncontrolled diabetic patients. Yet, zinc sulfate supplementation may be a therapeutical resource to recover some functioning and improve life span (Partida-Hernandez et al., 2006).

This article reports the effect of zinc sulfate on glucose and lipid profile of type 2 diabetes mellitus patients.

Materials and Methods: The study design was randomized, controlled trial. Subjects enrolled from Yazd Diabetes Research Center, Yazd, Iran. Inclusion criteria included type 2 diabetic patients with fixed drug dosage in past 6 months, fixed weight in past 3 months, without taking vitamins or mineral supplements in the previous 2 months and without clinical involvement of kidney, heart and lung. The subjects were fully informed of the purpose, procedures and hazards of trial and were free to leave the trial at any time. Written informed consent was obtained from all participants. The research protocol was approved by the ethics committee on human experimentation of Yazd University of Medical Sciences. Forty subjects divided randomly into two groups and supplemented daily with 660 mg zinc sulfate or placebo for six weeks. Zinc sulfate was manufactured by ALHAVI Company.

Subjects were instructed not to modify diet or activity level; each individual maintained dietary records at intervals throughout the experiment. Body Mass Index (BMI), Blood Pressure and biochemical markers included Fasting Blood Sugar (FBS), 2-h postprandial glucose (2hpg), Glycated hemoglobin (HbA1C), Triglyceride (TG), Cholesterol (chol), low -density lipoproteins (LDL), high - density lipoproteins (HDL), Blood Urea Nitrogen (BUN ), Creatinin (Cr), Alanine aminotransferases (ALT),Aspartate aminotransferases, (AST) were checked before the beginning of the study.

BMI was calculated as the weight in kilograms per the
square of height in meters and blood pressure measured with the person in the sitting position after a 5-min rest. All blood specimens were drawn at 8 a.m. after a period of 6 hours fasting. All patients were examined carefully and depending upon the treatment groups, each subject received drugs for a period of six weeks. Subjects eat zinc sulfate every eight hours by meal with a large glass of water (220 mg TDS).

BMI, blood pressure, AST, ALT and drug complications such as nausea, vomiting, abdominal pain, diarrhea, constipation, reduction of appetite were checked after 3 weeks.

At the end of 6 weeks all the indices checked as before the beginning and the drug complications were asked as well. Hba1C, BMI, blood pressure and complications were analyzed after 12 weeks to evaluate the long term effect of drugs.

Statistical analysis: All statistical analyses were performed by using SPSS, version 11.50. Data of continuous variables are expressed as means ± standard deviation. Differences between groups were assessed by the paired t test.

Results
All subjects completed the study. The mean age of patients was 52.67±8.80 with male constituting 40% of patients (16 male and 24 female). Mean duration of diabetes was 7.07±4.94 years. 17.5% and 22.5% of diabetic patients had hypertension and hyperlipidemia respectively, 65% and 62.5% ate metformin and glybenclamide respectively but only 5% had acarbose consumption. The characteristic and baseline biochemical markers of subjects are shown in Table 1. As it is seen in Table 2, level of FBS, 2HPP, Hba1C decreased after six week treatment with zinc sulfate but it was not statistically significant.

Due to zinc sulfate administration in diabetic patients, a significant decrease occurred in TG (P=0.005), chol (p=0.02), LDL (0.01) and systolic blood pressure (p=0.02).

Body Mass Index (BMI), Fasting Blood Sugar (FBS), 2-h postprandial glucose (2hpp), Glycated hemoglobin (Hba1C), Triglyceride (TG), cholesterol (chol), low - density lipoproteins (LDL), high-density lipoproteins (HDL), Systolic Blood Pressure (SBP), Diastolic Blood Pressure (DBP).

HDL was increased but it was not significant (p=0.14).
No statistically significant differences were found prior to and after zinc treatment in BMI and diastolic blood pressure.

Only two patients had mild abdominal pain. After 12 weeks, there was a significant decrease in Hba1C (P=0.04) in zinc sulfate group but a significant decrease didn't occur in BMI and blood pressure.

As it is seen in Table 2, no statistically significant differences were found prior to and after six weeks placebo treatment in different biochemical variables.

Discussion
Recently, diabetic patients have tendency to use complementary and alternative medicine beside routine therapies. Zinc is one of the minerals used by diabetic patients. Anderson et al. (2001) study on 110 type 2 diabetes mellitus with Hba1C > 7.5% revealed that more than 30% of the subjects may have been zinc deficient (Anderson et al., 2001).

In present study, no statistically significant differences were found prior to and after 6 weeks zinc sulfate treatment in FBS, 2hpp, Hba1C, HDL, BMI and diastolic blood pressure.

Body Mass Index (BMI), Fasting Blood Sugar (FBS), 2-h postprandial glucose (2hpp), Glycated hemoglobin (Hba1C), Triglyceride (TG), cholesterol (chol), low-density lipoproteins (LDL), high-density lipoproteins (HDL), Systolic Blood Pressure (SBP), Diastolic Blood Pressure (DBP). *Statistical significance when p<0.05.
Due to zinc sulfate administration in diabetic patients, a significant decrease occurred in TG (p=0.005), chol (p=0.02), LDL (p=0.01) and systolic blood pressure (p=0.02). After 12 weeks, there was a significant decrease in HbA1C (p=0.04).

Some investigations indicated that a zinc-enriched diet has beneficial effects on basal and postprandial glycaemia, the content of cholesterol and triglycerides (Ghayour-Mobarhan et al., 2005).

In Roussel et al. (2003) study on 56 diabetic patients (divided to zinc gluconate and placebo group) treated with 30 mg zinc gluconate, HbA1c decreased from 8.9±0.4 to 7.7±0.3% following six months of zinc supplementation, but decreases were not significant and no changes was seen in FBS (Roussel et al., 2003). Our result about FBS and HbA1c was similar to it.

Cunnane (1988) believed that zinc intimately affects many aspects of lipid metabolism through established enzymes but also has modulator effects whose mechanism is not obvious or established. In individuals with type 1 diabetes mellitus receiving 30 mg of zinc as zinc gluconate for three months, there were decreased lipid peroxidation and improvement in antioxidant status (Faure et al., 1995; Faure et al., 1993).

In Partida-Hernandez et al. (2008) survey on type 2 diabetic patients who received 100 mg zinc sulfate, there was no statistically change in FBS and HbA1C after 12 weeks (Partida-Hernandez et al., 2006). In our survey, HbA1C was statistically decreased after 12 weeks which may be related to the higher dosage of zinc sulfate in our study.

The diabetic patients had changes in their lipid profile after a 12-week zinc treatment as compared with placebo treatment in Partida-Hernandez et al. (2008) survey. The 100 mg zinc sulfate treatment was well tolerated, significantly reduced total cholesterol (p=0.01) and triglyceride concentrations (0.02) and increased those corresponding to zinc as well as HDL cholesterol in the bloodstream (0.002) but decrease in LDL was not significant (0.22) (Partida-Hernandez et al., 2006).

Differences with our study is related to drug dosage.

Results of randomized controlled trials of Hughes and Samman (2006) show that LDL, total cholesterol and triglycerides in plasma are unaffected by supplementation with up to 150 mg Zn/d. In contrast, HDL concentrations decline when zinc supplements provide a dose >50 mg/d (Hughes and Samman, 2006). Higher dose of zinc sulfate is needed to decrease the TG, total cholesterol and LDL similar to our study.

Hoppe et al. (1980) study examined the effect of zinc administration on serum lipoprotein values in man. Twelve healthy adult men ingested 440 mg of zinc sulfate per day for five weeks. High-density lipoprotein-cholesterol concentration decreased 25% below baseline values (40.5 to 30.1 mg/dL). Total cholesterol, triglyceride and low-density lipoprotein-cholesterol levels did not change throughout the study (Hoppe et al., 1980). In Roussel et al. (2003) study which indicated previously, no changes was seen in lipid profile (Roussel et al., 2003).

In Freeland-Graves et al. (1982) study, four levels of zinc supplements (0, 15, 50, or 100 mg/day) were given to 32 women for 8 weeks. No significant differences were seen in HDL-cholesterol over the 8 week except in the 100 mg group at week 4 (Freeland-Graves et al., 1982). In conclusion, it seems that zinc is a proper mineral in diabetic patients due to their deficiency and consumption of zinc sulfate in addition to other nutritional and pharmacological treatments in type 2 diabetic patients could be effective in lipid profile.
