Abstract: Partial pancreatectomy was performed in 7 dogs to obtain viable tissue as an alternative treatment of Diabetes Mellitus using a step denominated omentalation to avoid the formation of adhesions, reducing vomit and pancreatitis reported in other procedures. The results did not show pathognomic signs of Exocrine Pancreatic Insufficiency (EPI) or pancreatitis. The pain was alleviated with Meloxicam (0.2 mg kg⁻¹) IV and ketamine (intravenous infusion 0.5 mg/kg/hour). Glycemic values post surgery in the dogs stayed between 100 and 110 mg dl⁻¹ until the tenth day that concluded the study (mean 106.9 mg dl⁻¹). The test of plasma turbidity was realized to discard the EPI, being negative when there was a presence of turbidity 2 h after the administration of food added with corn oil. The technique of partial pancreatectomy in canine can be used to future transplants of islets of Langerhans. The glucose blood levels indicated that the resection of the left lobe of the pancreas did not affect the functional stability of the patient in short term.

Keywords: Pancreatectomy, dogs, surgery, pancreas, transplant

INTRODUCTION

Diabetes Mellitus is an endocrinopathy which alters the metabolism of carbohydrates, caused by a dysfunction of the islets of Langerhans from the pancreas causing a reduction of insulin secretion, resulting in hyperglycemia and glycosuria (Hall, 1997). The etiology is multi-factorial with different environment and genetic factors such as obesity which predispose the presentation of clinical diabetes (Loste et al., 2001). Recent studies have demonstrated that insulin therapy and a fibrous diet are not enough to compensate the glucose level in blood, reason why it has been explored the pancreas transplant as an alternative to compensate the damages caused by the partial or absolute deficiency of beta cells insulin producers (Liu and Herold, 2000; White et al., 2001). A pancreas transplant is a surgery to implant to a healthy pancreas from to donor into to patient with diabetes and give the patient the opportunity to become independent of insulin injections. The pancreas canine is characterized to show a substantial regenerative capacity. The resection in 75-90% of pancreatic tissue has demonstrated functionality, as long as the conduits have not been damaged during the intervention (Slatter, 2004).

Partial pancreatectomy, also well-known as distal pancreatectomy or hemipancreatectomy, is a surgical technique indicated in company animals for treatment of neoplasias, cysts, abscesses, traumasisms or biopsy (Stagner et al., 1991) and has been used in dogs since 1962 (Zafirov, 1962). Other procedures did not use the omentalization (Johnson and Mann, 2006) and present problems such as adhesions, autolysis by pancreatic enzymes, pancreatitis and vomit (Allen et al., 1989; Balcom et al., 2002; Ettinger and Feldman, 2002; Slatter, 2004).

Therefore, the objective was to perform partial pancreatectomy in dogs with omentalization to obtain viable tissue and diminish post surgical complications as a previous step in the pancreas transplant procedure.

MATERIALS AND METHODS

Procedures were realized in the Veterinary Clinic Unit of the Autonomous Metropolitan University Xochimilco. The anesthesia was in accordance with the Veterinary Clinic Unit, as accepted by the research and medical ethics committees of the Veterinary School. Six male and one female crossbred dog with and age between 2 and 5 years, with a mean weight of 15 kg were used.

During the first 2 days the dogs were bathed, housed in individual cages and fed with commercial diets (4140 kcal ME dm⁻³) and water ad libitum. The third day were fasted (food and water) during 10 h to perform the surgical technique of partial pancreatectomy.

Dogs were initially dosed with Acepromazine 0.1 mg kg⁻¹ i.m. and Butorfanol 0.1 mg kg⁻¹ s.c. The anesthesia was induced with Propofol 2 mg kg⁻¹ i.v and maintained with Isoflurane diluted in oxygen at 100% (Plumb and Pharm, 2002).

The surgical procedure started in the abdominal cavity performing an incision on the middle line. Then the fat and the subcutaneous tissue were dissected until the visualization of the white line. Then the omentum was retracted caudally to observe the pancreas (Fig. 1). Later the gastrocolic ligament was separated being exhibited both pancreatic lobes right and left, which were covered with compress dampened in saline solution at 0.9%. It was dissected the plane between the portal mesenteric and the later face of the neck of the pancreas (Fig. 2) using an absorbent polyglycolic acid suture (3-0) around the same realizing a surgeon knot applying the suture technique of fracture. On this way, the left lobe was free to be sectioned. At the end of surgical procedure, the remaining portion of the pancreas was covered with the greater omentum which was sutured with absorbent material polyglycolic acid suture (3-0) in order to provide irrigation to the pancreas. Finally, the cavity was closed by planes using the suture absorbent (3-0).

After 1 h of the surgery, sanguineous samples were collected to determine blood glucose levels with reactive strips (Dextrostix®) every 2 h during the first 3 days. Then during the following 6 days, glucose levels were checked twice per day (08:00 and 16:00). The dogs were maintained with solid restriction during 2 days. Subsequent to those days, the feeding began with the water ingestion and with canned food later with the diet for diabetic dogs from Hill's Pet Nutrition, Inc.

On day 9, tests were realized to discard Exocrine Pancreatic Insufficiency with the assay of turbidity of the plasma, observing the appearance of plasma (lipemia) that occurs 2 h after oral administration of 2 mL corn oil kg⁻¹ body weight. After 10 days, dogs were euthanized using sodic pentobarbitol (Sedalport®) 25 mg kg⁻¹ i.v. (Thurman et al., 1996). Post mortem examination was conducted to determine presence of pancreatitis, adhesions and ulcers, focal inflammation or multifocal inflammation caused by the distal pancreatectomy.

RESULTS AND DISCUSSION

In difference to other procedures reported in literature (Allen et al., 1989; Balcom et al., 2002), it was...
used a tie technique fractures, to only reitre a portion of pancreas (left lobe), without having to sacrifice the donor. The main difference in this procedure was step fractionated omentation (Johnson and Mann, 2006), that consists in placing the omentum on the zone of incision of the pancreas (Fig. 2). This action avoids the formation of adhesions and accelerates the healing process, reducing autolysis by pancreatic enzymes. This procedure result in abolition of vomit (Ettinger and Feldman, 2002) and pancreatitis reported in other procedures (Allen et al., 1989; Slatter, 2004). The omentation has been used to treat pancreatic abscess in dogs (Johnson and Mann, 2006).

During the first 2 days after surgery, all the dogs showed pain degree five according to Holton (2001), manifesting vocalizations, pale mucous, retraction of the labial commissures, muscular tremor generalized, resistance to movement, bent position and “prayer” position, accentuating more in 2 dogs (numbers 1 and 2). Pain was associated to the manipulation of the pancreas (Garcia, 2001).

The administration of Meloxicam 0.2 mg kg⁻¹ i.v. and ketamine in infusion intravenously (0.5 mg kg⁻¹ of BW) during 24 h was satisfactory to alleviate the pain, showing improvements after 24 h post-administration. Only 2 dogs lose weight (numbers 1 and 4) and at the end of the period, most of the dogs showed a positive energy balance (Table 1).

The blood glucose levels in the dogs during the experiment stayed between 100 and 110 mg dL⁻¹ without any episodes of hyperglycemia or hypoglycemia (Table 1). Those values indicated that the pancreas maintained its function integrity after the surgery.

The vomit was observed in two dogs the second day and in one the third day post surgery, when solid food was offered in small portions. Diarrhea was presented in one dog on the seventh day. None of the dogs show any sign of Exocrine Pancreatic Insufficiency (EPI) according to the qualitative test of turbidity of the plasma. It is possible that EPI signs were not detected because it appears 3 months after the intervention of the pancreas (Kogire et al., 1993) which is an autoimmune process with total destruction of pancreatic parenchymal. However, there was no presence of any sign such as dramatic weight loss, intake disorders and feces voluminous which indicates the presence of EPI (Wiberg and Westermark, 2002; Moeller et al., 2002).

On day 3 after the intervention, all the dogs responded positively accepting water for drink and solid food, without diarrhea or flatulence. The emesis and anorexia was not associated with pancreatitis (Allen et al., 1989). Ettinger and Feldman (2002) have associated the vomit and the diarrhea with inflammation of the small intestine in the procedure of partial pancreatectomy.

The post-mortem examination showed adhesions from the greater omentum with the ventral part of the stomach and duodenum, without characteristic lesions of pancreatitis. Allen et al. (1989) reported lesions of pancreatitis in dogs subjected to pancreatectomy. In this study, none canine presented hemorrhage. Only 1 dog showed pancreatitis, presence of focal and multifocal fibrosis and an apparent pancreatic fistula. Balcom et al. (2002) reported the formation of pancreatic fistula as a consequence of the partial pancreatectomy, from 15-25% of the cases. This complication was avoided using synthetic absorbent material in the portion of the pancreas which is separated.

**CONCLUSION**

The procedure to perform a partial pancreatectomy described here can be used to obtain viable pancreatic tissue as a previous step in a pancreatectom in dogs. The blood glucose levels indicated that the integrity of the pancreas was not affected in the dogs. The post mortem examination indicated that the complications of pancreatic fistula represented only 14% (1 in 7 dogs) which is lower percentages reported with the procedure. In short term Exocrine Pancreatic Insufficiency was not presented, however, long term studies are required to evaluate the complete efficacy of this procedure.
