Abstract: The objective of this study was to investigate the coagulation disorders in drought horses suffering from colic. A total of (125) local drought male horse of different ages were investigated, among these animals (100) were suffering colicky sings and (25) clinically normal drought male horses served as control. Results indicated that colicky horses showed sings of pain which manifested by, restlessness, anxiety, sweating, lip curling, flank watching, pawing at the ground, kicking at the belly and rolling, more over body temperature, respiratory and heart rate, capillary refilling time were also increased, petechial hemorrhages were also detected on mucus membranes of the eyes. The statistical analysis appeared significant decrease (p<0.05) in the TRBCs, Hb in horses suffering the recurrent type of colic compared with animals suffering the acute, mild type and control normal horses and PCV were significantly higher (p<0.05) in diseased horses than in normal control animals. Data concerning the indices of clotting factors of normal control and colicky horses showed that the platelet count and fibrinogen was lower significantly (p<0.05) in diseased horses than in control normal horses. This count was significantly lower in horses suffering the acute and recurrent type of colic than horses suffering the mild type. The platelet volume, platelet distribution width clotting time, prothrombin time and activated partial thromboplastin time values were significantly higher (p<0.05) in diseased horses suffering the acute and recurrent type of colic than in diseased horses suffering the mild type and normal control animals. Results of biochemical changes indicated significant decrease (p<0.05) in total protein and albumin in colicky horses showed the mild and recurrent type of colic where as significant increase (p<0.05) of same values were seen in animals suffering the acute type, further more significant decrease (p<0.05) in calcium values were encountered in horses suffering the acute and recurrent type of colic.

Key words: Equine colic, hematology, indices of clotting factors, drought, significant, diseased

INTRODUCTION

Colic is a general term indicating abdominal pain, (Abutarbush et al., 2005). It is not a disease but a combination of signs that alert us to abdominal pain in the horse (Aiello, 1998). Colic is the single most important cause of death in horses (Archer et al., 2006). The reaction of a horse to abdominal pain were kicking, rolling, sweating and others, which can originate from stomach, small intestine or the large intestine, (True colic), or other organs (False colic) (Hewetson, 2006).

There are a variety of different causes of colic, as dietetic causes concerned with quality and quantity of feeding, gastro-intestinal accidents, gastro-intestinal worms infestation, urinary tract dysfunction, exhaustion due to hard work, seems to be the most common (Radostitis et al., 2000).

Hemostasis is a complex process with positive and negative regulators for formation and degra-dation of fibrin (Prasse et al., 1993). Imbalanced regulation may lead to hyper coagulation (Thrombosis), hypo-coagulation (Hemorrhage), or paradoxically to both of them (Byars, 1987; Collatos et al., 1995; Petterson et al., 1995). Haemostatic abnormalities such as thrombo-cytopenia, prolonged clotting times, prothrombin time, activated partial thromboplastine time, increased fibrinogen degradation products activity have been reported in horses with colic (Parry, 1987; Monreal et al., 2000; Monreal and Cesurini, 2009).

Primary hemostasis can be evaluated by determination of platelet numbers, platelet volume and platelet distribution width, more over secondary hemostasis can be evaluated by the activated partial thromboplastin for intrinsic and common pathway abnormalities, fibrinogen quantification (common pathway abnormalities) and prothrombin time for extrinsic and common pathway abnormalities (Welch et al., 1992).

The purpose of this study was to determine the abnormalities of hemostatic profiles in drought horses suffering from colic in Mosul, Mosul-Iraq.

MATERIALS AND METHODS

Animals and study design: The study was conducted on 125 local drought male horses of different ages, among these 100 animals were naturally suffering from colicky signs and 25 clinically normal horses served as control. Diseased animals were divided into three groups according to severity of colic, as (20) suffering from mild type of colic, (47) from acute (severe) type and (33) from the recurrent type. The study was carried out in Mosul (Mosul-Iraq). Careful clinical examination had been carried out in all animals and fecal samples were screened for parasitic load using standard technique.

Blood collection and hematology: Ten milliliter of blood were drained from each animal by jugular vein-puncture, from these 2.5 mL of blood mixed with EDTA used to determine total erythrocyte count (TRBCs), Hemoglobin concentration (Hb), Packed Cell Volume (PCV), Platelets count (Plt), Mean Platelets Volume (MPV), Platelets Distribution Width (PDW), (Automatic Full Digital cell Counter, Beckman, USA), another 2.5 mL of blood mixed with Trisodium citrate (used plasma) were used to determine prothrombin time (Prt) and activated partial thromboplastin time (Aptt) (Coles, 1986). Clotting Time (CT) was also estimated according to (Bush, 1975).

Blood serum samples were tested spectrophotometrically for total protein, albumin, globulin calcium and fibrinogen, using available kits (Biolabo, France).

Statistical analysis: The significance of variations in the various values of diseased horses and those of normal control animals were analyzed statistically using SPSS (Leech et al., 2007).

RESULTS

Diseased horses showed different clinical signs including, signs of pain which manifested by, restlessness, anxiety, sweating, lip curling, flank watching (Fig. 1), pawing at the ground (Fig. 2), kicking at the belly and rolling, more over body temperature, respiratory and heart rate, capillary refilling time were also increased, petechial hemorrhages were also detected on mucus membranes of the eyes. Statistically significant decrease (p<0.05) were encountered in TRBCs, Hb in horses suffering the recurrent type of colic compared with animals suffering the acute, mild type and control normal horses, PCV were significantly higher (p<0.05) in diseased horses than in normal control animals (Table 1).

Fig. 1: Looking at flank region

Fig. 2: Pawing at the ground

Data concerning the indices of clotting factors of normal control and colicky horses are presented in Table 2. The platelet count and fibrinogen was lower in diseased horses than in control normal horses. This difference was statistically significant (p<0.05). This count was significantly lower in horses suffering the acute and recurrent type of colic than horses suffering the mild type. The platelet volume, platelet distribution width clotting time, prothrombin time and activated partial thromboplastin time values were significantly higher (p<0.05) in diseased horses suffering the acute and recurrent type of colic than in diseased horses suffering the mild type and normal control animals.

Results of biochemical changes indicated significant decrease (p<0.05) in total protein and albumin in colicky horses showed the mild and recurrent type of colic, where as significant increase (p<0.05) of same values were notice in animals suffering the acute type of colic, further more significant decrease (p<0.05) in calcium values were also encountered, in horses suffering the acute and recurrent type of colic (Table 3).

**DISCUSSION**

In current study, colicky horses showed different clinical sings, as songs of pain which manifested by, restlessness, anxiety, sweating, lip curling, flank watching, pawing at the ground, kicking at the belly and rolling, were more prominent, more over body temperature, respiratory and heart rate, capillary refilling time were also increased, beside the presence of petechial hemorrhages on mucus membranes of eyes, those signs were in agreement with others (Radostitis et al., 2000; Pratt et al., 2003), severity of signs were different according to severity of the disease (mild, acute and recurrent) (Sharky et al., 2006). Clinical and laboratory findings as well as coagulation profiles changes on the basis of severity of colic in horses were also reported (Parry, 1987; Henry and Moore, 1991; Prasse et al., 1993; Topper and Prasse, 1998). Colic in horses very often induces changes in the coagulation system causing the development of disseminated intravascular clotting (Monreal and Cesaremi, 2009). It is promoted by blood concentration and an increase in exposition of coagulation activators with a simultaneous decrease in coagulation inhibitors activity (Stokol et al., 2005). The most common coagulopathy in horses with colic is a hypercoagulable state associated with disseminated intravascular coagulation and the intensity of this coagulopathy depends on the severity and duration of the gastrointestinal lesions or other causes of colic, with the ischemic and inflammatory problems and peritonitis being the most frequently affected by coagulopathies (Collatos et al., 1995). In current study, results showed decrease values of total platelet count, fibrinogen as well as increase platelet volume and its distribution width, beside increase values of clotting time, prothrombin time and activated partial thromboplastin time specially in horses suffering the acute and recurrent type of colic, these results were also mentioned by Johnstone and Cdale (1986), Prasse et al. (1993), Monreal et al. (2000) and Imaz et al. (2002) as thrombocytopenia, hypofibrinogenemia and decrease clotting time of the blood were reflected the petechial hemorrhages seen on mucus membranes of colicky horses and the prolongation of capillary refilling time (Edwards, 1998) moreover, this might attributed to the release of endogenous mediators such as platelet activating factor in inflammatory disorders (Zbynszek et al., 2004). Any bleeding tendency were occur in the body regions must followed by the process of clotting and there are sever factors play an important role in this process such as vascular factors (which is characterized by a rapid response, is narrowing and contraction of the vessel, causing decreased pumping mechanism of the blood) and are directly related to the integrity of blood vessels, more over the numbers of blood platelets and activity have significant role in the process of coagulation, in which the accumulation of blood platelets (Platelets aggregates) and then its adherence within the vessel wall causing Platelets thrombus (temporary plug) (Smith, 1996). Depression of platelets number may also occur due to depression of bone marrow activity, splenomegaly and platelets sequestration (Rehar et al., 2005). The clotting phase (Coagulation) considered as the final stages of the clotting mechanism which are activated by such factors as, Hageman factor (XII), Plasma thromboplastin antecedent factor (XI) and Thromboplastin component (IX) in the form of cascades, which are responsible for transforming prothrombin to thrombin and the fibrinogen to fibrin, resulting in deposition of Fibrin clot within the blood vessels (Smith, 1996), which will lead to disorganization of hemostatic mechanism causing micro thrombosis and infarction of specific organs (Bick, 2003). It has been reported that prolonged PT and APTt was the most frequently observed abnormality in the coagulation profile and was more likely to be prolonged in horses with colic that did not survive (Michelle and Moore, 1991; Imaz et al., 2002).

There were significant reduction seen in total protein and albumin in horses suffering from the mild and recurrent type of colic which were agree with (Topper and Prasse, 1998) whose stated that decrease protein levels in colicky horses may occur due to gastro-intestinal accident
CONCLUSION

Equine colic were affected drought horses and exhibited different clinical signs and a significant changes were noticed between diseased and control animals concerning the indices of clotting factors, very often induces changes in the coagulation system causing the development of disseminated intravascular clotting and high mortalities of colicky horses will follow.
