The Effect of Ivermectin Pour-On Administration Against Natural
*Trichostrongylus colubriformis* Infestations and Prevalence Rate of that in Cattle

**Abstract:** These days one of the real problems that cause the prejudice economic in animal farms yearly is parasitic diseases. For that reason to prevent these problems, the use of antiparasitic drugs is necessary. Ivermectin is a broad spectrum antiparasitic agent and different dosage forms such as injection, oral and pour-on use. The aims of this study was evaluation of the efficacy of ivermectin pour-on administration against natural *Trichostrongylus colubriformis* nematode infections in cattle and also determine the prevalence rate of this parasite in Tabriz area. In this study, 120 heads of male and female hybrid cattle were carried out LPG (Larves Per Gram of feces) feces test. Willis method was applied for feces test and Stoll method was used for counting nematode larvae (LPG). After confirm worm contamination and counting *Trichostrongylus colubriformis* nematode larvae in feces in infected animals, ivermectin (0.5 mg kg⁻¹) pour-on was administered. Feces test was repeated in 1st, 7th, 21st and 28th day after treatment. Results showed that total prevalence of *Trichostrongylus colubriformis* nematode infections was 20% in cattle's of Tabriz area. The effects of ivermectin pour-on on *Trichostrongylus colubriformis* nematode were 40, 79.23, 93.84 and 99.23% in 1st, 7th, 21st and 28th days, respectively.

**Key words:** Ivermectin, pour-on administration, *Trichostrongylus colubriformis*, cattle, infections, Iran

**INTRODUCTION**

Infections with Gastrointestinal (GI) nematodes are very common on cattle farms in Iran and all over the world. Parasitic infections of cattle's are major factors responsible for economic losses through reduction in productivity and increased mortality. Parasites cause the animals to be unthrifty which mayinclude the loss of weight, low birth weights and difficulty in kidding. Due to parasitism, the animals become susceptible to other health problems which can lead to death. However, there is substantial evidence that they can also exert important negative effects on the productivity of adult dairy cows (Sanchez et al., 2004). Many researchers for prevalence rate of gastrointestinal parasites in all the word have been reported but research for effect of anti parasitic drug by different administration ways is low and in Iran, the study on present subject has not been done (Chaudhri et al., 2003; Georgi et al., 1990; Kassai, 1999; Mandal, 2006; Soulsby, 1986, Urquhart et al., 2003). Ivermectin is a member of the macrocyclic lactone class of endectocides, commonly referred to as avermectins. It is labeled for the treatment of internal and external parasites in dogs, cats, horses, pigs, sheep and cattle. Subcutaneous (SC) and Topical (TOP) formulations are available for use in non-lactating dairy cattle at a dose of 0.2 and 0.5 mg kg⁻¹ Body Weight (BW), respectively. Ivermectin is a highly potent broad-spectrum anthelminthic that is widely used in cattle. It is available in injectable, oral and topical formulations for use in cattle (Vermunt et al., 1995). The most important GI nematode responsible for considerable production losses in cattle is *Trichostrongylus colubriformis* (Armour, 1989). By attention to this subject which in Iran study on pour on administration of ivermectin on *Trichostrongylus colubriformis* has not been done and the facile use of this drug. The objective of this study were to determine the evaluation of the effect of ivermectin pour-on administration against natural *Trichostrongylus colubriformis* nematode infections and prevalence rate of them in cattle. This study is the 1st report in Iran.

**MATERIALS AND METHODS**

In present study, a total number of 120 dubious cattle to *Trichostrongylus colubriformis*infestation from 50 different farms in Tabriz area for fecal examination and LPG were collected. After 3times fecal examination, a total number of 120 cattle infected to *Trichostrongylus colubriformis* were distinguished and after this step,
infected cattle's isolated and then pour on ivermectin at a dose of 0.5 mg kg$^{-1}$ were administrated. Also, pour on form of ivermectin by melting the ivermectin powder in solution of isopropyl alcohol (weight-weight) with 3.5% concentration were made (Reinemeyer and Courtney, 2001). In this study for differential diagnostic of cooperia oncophora larvae from other larvae of authentic book were used (Soulsby, 1986), also for exact distinguish from fecal culture and shape of L$_3$ (3rd stage form of larvae) were used (Georgi et al., 1990; Kassai, 1999; Soulsby, 1986; Urquhart et al., 2003).

After and before the beginning of cattle treatment in 3 times fecal samples taken for fecal examination and after examination, results of larvae enumeration in one designed form were written. Fecal examination in day 1st, 7th, 21st and 28th after treatment were repeated. In this study for fecal examination from Willis method and for larvae examination (LPG) of Stool method were used (Rehbein et al., 1999).

In this study following equation for determine the effective rate of pour on administration of ivermectin were used:

$$\text{Efficacy of drug (\%) = } \frac{P - R}{P} \times 100$$

Where:
- $R$ = Average of parasite larvae number in g of fecal sample after treatment
- $P$ = Average of parasite larvae number in g of fecal sample before treatment

Data were analyzed by non-parametric cross-sectional and p<0.05 was considered significant (Aguirre et al., 2005; Colwell and Jacobsen, 2002).

**RESULTS AND DISCUSSION**

The results of present study indicated which from 120 cattle's, 24 head of them infected to Cooperia oncophora were distinguished and prevalence rate of this parasite 20% were calculated. Average number of enumerated larvae in fecal samples of different days after treatment with pour on ivermectin in Table 1 has been showed. The rate of ivermectin pour on administration affect in different days after treatment by formal was calculated and in day 1st, 7th, 14th and 21th was respectively 40, 79.23, 93.84 and 99.23. The ivermectin pour on administration reduced the natural parasite infestation (Table 2). According to results of cross-sectional and p<0.05 was considered significant (Aguirre et al., 2005; Colwell and Jacobsen, 2002).

The effect rate of ivermectin on this parasite is >99%. In these days, ivermectin have different drug shapes. Half time of intravenous administration of ivermectin with dose of 300 µg kg$^{-1}$ in cattle is 2.8 days but in subcutaneous administration with dose of 200 µg kg$^{-1}$ is 8th day and also has been showed that the effect of sustained-release administration of this drug in cattle is very more than to oral and subcutaneous administration of that (Reinemeyer and Courtney, 2001). The importance base in use of antiparasitic drugs is the increase of contact time of drugs with parasites is very effective in comparison with increase the dose of these drugs (Georgi et al., 1990; Kassai, 1999; Reinemeyer and Courtney, 2001; Soulsby, 1986; Urquhart et al., 2003). This subject has been demonstrated that ivermectin with dose of 1 mg kg$^{-1}$ (oral or injection) have effective antiparasitic role in veterinary. The dose of this drug in cattle for oral and subcutaneous administration is 0.2 mg kg$^{-1}$ and for pour on administration is 0.5 mg kg$^{-1}$, these doses of ivermectin have importance antihelminthic effect between 97-100% on adult form and L$_4$ (4th stage of larvae) of Haemonchus, Ostertagia, Cooperia, Trichostrongylus, Strongyloides, Bonostomum, Nematodirus, Trichuris, Oesophagostomum, Dictyocaulus and Chabertia ovina, also with these doses have effective role in reduce of some arthropods (Georgi et al., 1990; Kassai, 1999; Reinemeyer and Courtney, 2001; Soulsby, 1986; Urquhart et al., 2003). According to findings of researchers, tablet form of ivermectin with dose of 0.2 mg kg$^{-1}$ causes reduce in eggs in feces during 10 weeks after treatment but have not protective role for reinfection of cattle with one dose of drug administration. Subcutaneous administration of ivermectin with dose of 0.2 mg kg$^{-1}$ and pour on of that with 0.5 mg kg$^{-1}$ dose have high effective role for control of parasites, also have importance protective role for reinfection in cattle's. Also according to findings of researchers one administration of ivermectin with dose of 0.5 mg kg$^{-1}$ have high effect between 95-100% on Haemonchus, Oesophagostomum and Bonostomum (Egerton et al., 1981; Garg et al., 2007;
Reinemeyer and Courtney, 2001) and when ivermectin with present dose used in this time have importance effect on Boophilus, Damalina and others arthropods (Barth and Preston, 1988; Borges et al., 2008; Colwell and Jacobsen, 2002; Lonneux et al., 1997; Marley et al., 1993; Reinemeyer and Courtney, 2001). Doramectin administration (with ivermectin are in one family) after 14 and 21 days, respectively 99.2 and 90.7% on Cooperia after 21 and 28 days, respectively 99.9 and 93.7% on Ostertagia after 21 and 28 days, respectively 100 and 99.9% on Haemonchus and Bursatella have importance effect. In one study on natural infestation of cattle's, doramectin causes deleting this infestation to Ostertagia and Cooperia, respectively in days of 19th and 22nd. By attention to this subject that effect of drug on most parasites is after day of 14th therefore, permanent of drug on surface of body have very importance in effective rate of drugs (Reinemeyer and Courtney, 2001).

In present study, effective rate in day of 28 after treatment by pour on ivermectin administration on Trichostrongylus colubriformis, 99.23% determined which with calculated effective rate of Gill and Lacey (1998) have a low different. Williams in one study on natural infected cattle's to Ostertagia, Cooperia, Oesophagostomum, Trichostrongylus, Haemonchus and Bursatella with comparison, the effect of injection doramectin and ivermectin with pour on ivermectin shows which these 3 drugs causes decrease the number of eggs and larvae of these parasites in feces and from effect comparison aspect, these drugs have not considered different and they reported which pour on administration of these is similar to injection administration (Williams et al., 1997a). In study by Eyker indicated which this drug have protective effect on cattle and causes reduce the specific antigen of Cooperia oncophora (Eyker et al., 1998). In other study by Williams on comparison, the effect of pour on administration of ivermectin, doramectin, ivermectin and moxidectin shown that maximum and minimum effect was with ivermectin and moxidectin observed, respectively (Williams et al., 1999). In one study on comparison the effect of suspension albendazole, oxendazole and fenbendazole with pour on ivermectin on gastrointestinal and respiratory nematodes indicated which maximum effect was with pour on administration of ivermectin with 99.2, 98.3 and 98.1% effect on Ostertagia, Cooperia and Dietyocaulus, respectively and minimum rate was with fenbendazole (63.6, 17.7 and 39.7) and oxendazole (78.5, 42.1 and 32%) (Williams et al., 1997b).

Gaylard et al. (1999) says that can use of ivermectin and doramectin for control of gastrointestinal parasites in cattle (Gaylard et al., 1999). Whang has been reported which pour on and injection administration of moxidectin have positive effect >90% on Ostertagia and Cooperia and significant different between these two type of administration were not reported (Whang et al., 1994). In two studies by Williams indicated that moxidectin have very importance role for control of parasitic disease (Williams et al., 1996, Williams ans De Rosa, 2003). Skogerboe and Rehbein reported that pour on administration of ivermectin during rain too have antiparasitic effect >90% and rain have not specific effect on reduction the role of ivermectin (Rehbein et al., 1999; Skogerboe et al., 1999) of course, other studies on this subject has been done and indicated that during raining pour on ivermectin is active against parasites (Rehbein et al, 1999; Rolfe et al., 1997; Skogerboe et al., 1999). In fact, pour on administration of ivermectin is very easy for farmers and so far for this way of ivermectin administration any specific side effect has not been reported (Reinemeyer and Courtney, 2001). In end can say, ivermectin is very effective drug for control of gastrointestinal parasites in ruminant and use of that is very easy and have not need to specific tools. Of course, effect of pour on administration of ivermectin on other helminths and arthropods need to more studies.

CONCLUSION

In this study because the effect of this drug against Trichostrongylus colubriformis nematode was >99% (p<0.05) so in cattle can use this drug in antiparasitic program. Of course, the effect of this drug on other nematodes and parasitic infections are needed to be more investigated.
