Polymorphism of Human (CTLA4) Gene and Insulin-Dependent Diabetes Mellitus Associated with Obesity in Iraqi Population

Shatha Ramadhan Zaidan
Alkindy Medical College, Baghdad University, Baghdad, Iraq

Abstract: The cytotoxic T Lymphocyte-Associated Antigen 4 gene (CTLA4) encodes the T cell receptor involved in the control of T cell proliferation and mediates T cell apoptosis. The receptor protein is a specific T lymphocyte surface antigen that is detected on cells only after antigen presentation. Thus, CTLA4 is directly involved in both immune and autoimmune responses and may be involved in the pathogenesis of multiple T cell-mediated autoimmune disorders. In this research the work was to investigate whether this gene conferred susceptibility to IDDM in a Russian population. The researchers carried out family studies using two polymorphic markers at the CTLA4 gene locus: codon 17 dimorphism and the dinucleotide microsatellite in the 3' untranslated region. The Ala17 allele of the CTLA4 gene was preferentially transmitted from parents to diabetic offspring (p<0.0001) as shown by the combined Transmission/Disease Test (TDT) and Sib TDT (S-TDT) analysis.

Key words: Polymorphism, (CTLA4) gene, diabetes mellitus, transmission, diabetic, Iraq

INTRODUCTION

The cytotoxic T Lymphocyte-Associated Antigen 4 gene (CTLA4) encodes the T cell receptor involved in the control of T cell proliferation and mediates T cell apoptosis (Morrison, 1997). The receptor protein is a specific T lymphocyte surface antigen that is detected on cells only after antigen presentation. Thus, CTLA4 is directly involved in both immune and autoimmune responses and may be involved in the pathogenesis of multiple T cell-mediated autoimmune disorders.

The human CTLA4 gene was mapped to chromosome 2q33 (Saleh et al., 2008). It consists of three exons. The first encodes a V-like domain of 116 amino acids. An A to G substitution at nucleotide 49 in exon 1 results in an amino acid substitution (Thr/Ala) in the leader peptide of the protein (Dejkhamann et al., 2007). The Ala allele has been shown to predispose the individual carrying it to the development of various immune diseases including Graves disease (Mei et al., 2007), Hashimoto’s thyroiditis (Oliver and Silman, 2009), Addison’s disease (Oliver and Silman, 2009), rheumatoid arthritis (Becker, 2004; Boright, 2008), celiac disease (Bergfeldt, 2009; Vidal et al., 2008) and others (Abraham et al., 2008). The Thr17Ala dimorphism and the polymorphic (AT)n microsatellite starting at position 642 of the 3' untranslated region flanking exon 4 of the CTLA4 gene and located 5.3 kb 3' of the biallelic codon 17 were shown to be linked to and associated with Insulin-Dependent Diabetes Mellitus (IDDM) in Italian diabetic families (Van Den Berg et al., 2007). Van Den Berg et al. (2007) led to refer to the susceptibility to diabetes associated with CTLA4 as IDDM12. Further evidence for an IDDM susceptibility locus on chromosome 2 in 2q33, the region containing the CTLA4 gene has been provided from various ethnic groups including Caucasians (British, Spanish, French, Swedish and Belgian), Mexican-Americans and Asians (Korean, Chinese and Japanese) (Do and Kim, 2010; Trayhurn, 2011). In contrast, a lack of association of the CTLA4 gene with IDDM was observed in other Caucasian populations including Sardinians (Mangee et al., 2011), Germans (Bell et al., 2005), Danish (Fawcett and Barroso, 2010; Lee, 2009) and U.S. whites (Ohman, 2001; Langberg, 2010). The researchers therefore, decided to investigate whether this gene conferred susceptibility to IDDM in a Russian population. The researchers carried out family studies using two polymorphic markers at the CTLA4 gene locus: codon 17 dimorphism and the dinucleotide microsatellite in the 3' untranslated region.

MATERIALS AND METHODS

Subjects and DNA extraction: Whole blood samples was obtained from 20 Iraqi patients affected by IDDM (10 male and 10 female, age ranged 4-25 years) and also obtained from healthy men were used to determine the PCR specificity and sensitivity. In each case, 4 mL of whole blood was collected into an EDTA-tube; the samples were stored at -20°C until further processing. DNA was extracted from the samples by wizard genomic (DNA
purification kit, Promega) according to the isolating genomic DNA from whole blood protocol. DNA extracted from 300 μL whole blood in each case. The volume of the extracted DNA solution was usually 100 μL were stored at -20°C.

**PCR amplification and genotyping:** A 152 bp fragment containing the +49 A/G polymorphism in exon 1 of CTLA4 was amplified using a forward primer (CTLA4-5': 5'-AAGGCCTGAGCTGAACTCCTG-3') and a reverse primer (CTLA4-4: 5'-CCTGCTGAAACAAATGAAACCC-3'). The forward primer was designed with a single base mismatch for the last nucleotide which corresponds to the +47 position to introduce a base change in the sequence of the PCR product according to (Morran, 1997) (Primers set supplied by alpha DNA Company).

The PCR amplification was performed in a total volume of 25 μL containing 5 μL DNA (conc. 20 ng), 12.5 μL GoTaq green master mix 2X (green master mix is a premixed ready to use solution containing Taq DNA polymerase, dNTPs, MgCl2, and reaction buffers at optimal concentrations for efficient amplification of DNA template by PCR supplied by promega (Promega corporation, USA). About 1 μL of each primer (50 pmol/μL) and up to 25 μL with nucleases free water.

The thermal cycling was as follows: denaturation at 94°C for 5 min followed by 30 cycles of 94°C for 30 sec, 57°C for 1 min and 72°C for 1 min with final incubation at 72°C for 7 min using a thermal cycler (Gene Amp, PCR system 9700, Applied Biosystem).

The PCR products were separated by 1.5% agarose gel electrophoresis and visualized by exposure to ultraviolet light (302 nm) after ethidium bromide staining. The substitution creates a BstEI restriction site in the A allele and this will be confirmed by incubated the PCR Amplified products (12 μL) with 5 U of BstEII (supplied by Promega corporation, USA) per reaction at 60°C over night. Digested products were electrophoresis on 2.5% agarose gel. The digested A allele yields a fragment of 130 bp and the G allele yields an intact 152 bp fragment.

**RESULTS AND DISCUSSION**

The Ala17 allele of the CTLA4 gene was preferentially transmitted from parents to diabetic offspring (p=0.0001) as shown by the combined Transmission/Disequilibrium Test (TDT) and Sib TDT (S-TDT) analysis. A significant difference between diabetic and non-diabetic offspring was also observed for the transmission of alleles 17, 20 and 26 of the dinucleotide microsatellite. Allele 17 was transmitted significantly more frequently to affected offspring than to other children (p = 0.0112) whereas alleles 20 and 26 were transmitted preferentially to non-diabetic sibs (p = 0.045 and 0.00068, respectively). A nonrandom excess of the Ala17 CTLA4 molecular variant (Maximum Logarithm of odds Score (MLS) of 3.26) and allele 17 of the dinucleotide marker (MLS = 3.14) was observed in IBD-affected sibling pairs. Figure 1 shows PCR product of (FTO) gene electrophoresis on agarose gel (2%), 45 min/70 V and the reaction was carried out as

CONCLUSION

A significant difference between diabetic and non-diabetic offspring was also observed for the transmission of alleles 17, 20 and 26 of the dinucleotide microsatellite. Allele 17 was transmitted significantly more frequently to affected offspring than to other children (p = 0.0112) whereas alleles 20 and 26 were transmitted preferentially to non-diabetic sibs (p = 0.045 and 0.00068, respectively).
