Abstract: The cannabinoids are found to have particular application as neuroproteactants for mental and motor dysfunction in neurodegenerative diseases. The neuroprotective properties of cannabinoids suggest their therapeutic use for limiting neurological damage. The cannabinoids treatments should not only aim to alleviate specific symptoms but also, attempt to delay/arrest disease progression and to repair the damaged structures. The researcher conducted a review of studies published between 1974 and 2011. The search was performed using the following PubMed search terms: “Cannabinoids” and “Neurodegenerative Diseases” and 287 papers were detected. The study were examined and the overlapping or insufficiently clear works were excluded. Finally, we chose 117 articles regarding the latest international guidelines, the pathophysiology of neurodegenerative diseases and the various therapeutic choices. The studies reported in the present review support the view that the cannabinoid signalling system is a key modulatory element in the activity of the basal ganglia. This idea is supported by different anatomical, electrophysiological, pharmacological and biochemical data. Furthermore, these studies indicate that the cannabinoid system is impaired in different neurological disorders that directly or indirectly affect the basal ganglia which supports the idea of developing novel pharmacotherapies with compounds that selectively target specific elements of the cannabinoid system.

Key words: Cannabinoids, mental and motor dysfunction, neuroprotection, system, element, activity

INTRODUCTION

The recreational use of Cannabis sativa preparations is known to most people (Adams and Martin, 1996). However, the medicinal use of Cannabis also has a millenarian history that has been re-examined only very recently (Williamson and Evans, 2000). As early as 2600 BC, the Chinese emperor Huang ti advised taking Cannabis for the relief of cramps and rheumatic and menstrual pain (Mechoulam, 1986a, b). This long history of Cannabis medical use has resulted in the development of pharmaceutical drugs such as Dronabinol and Cesamet. These preparations are based on Δ9-tetrahydrocannabinol (THC, Fig. 1) which in 1964 was identified by Mechoulam and coworkers as the major psychoactive component of Cannabis. They are prescribed in the United States as anti-emetic and appetite-stimulants to patients with cancer and AIDS. To date, some 60 plant terpenophenols more or less related to THC have been isolated and defined cannabinoids (Mechoulam and Gaoni, 1967).

Δ9-tetrahydrocannabinol for its potency and abundance in Cannabis is the most important.

Cannabinoid receptors: Thus far, 2 cannabinoid-specific receptors have been cloned and characterized from mammalian tissues, the 7 transmembrane G protein-coupled cannabinoid receptors type 1 (CB1 receptor) (Matsuda et al., 1990) and type 2 (CB2 receptor) (Munro et al., 1993). Whereas the CB1 receptor expression is abundant in the central nervous system, the CB2 receptor is almost exclusively expressed in the immune system. The CB1 receptor is also, expressed in peripheral nerve terminals and various extraneuronal sites such as the testis, uterus, eye, vascular endothelial, spleen and adipocytes (Howlett, 2002, 2005; Herkenham et al., 1991; Porter and Felder, 2001).

Pharmacological evidence exists for the presence of other cannabinoid receptors which, however, have not yet been cloned (Begg et al., 2005).

CB1 and CB2 receptors share only 44% overall identity and 68% within the transmembrane domains. Both cannabinoid receptors are coupled to G proteins, mostly of the G12 type, through whose α subunit they inhibit the activity of adenylate cyclases and stimulate mitogen-activated protein kinases. However, additional studies established that cannabinoid receptors were also, coupled to ion channels, resultant in the inhibition of Ca2+ influx through N type calcium channels (De Fonseca et al., 2004). CB1 receptors are also, implicated in activation of both phospholipase C (via, the βγ subunits of the G protein) and PI-3-kinase. CB2 receptors, on the other hand, trigger a sustained activation of ceramide biosynthesis (Howlett et al., 2014).

**MATERIALS AND METHODS**

The endocannabinoid system: Several endogenous fatty-acid ligands, known as endocannabinoids have been identified as having activity at the cannabinoid receptor. The first to discovered in 1992 was arachidonoyl ethanolamide (Anandamide, AEA) followed by 2-Arachidonoyl Glyceryl (2-AG). Both these compounds are derivatives of arachidonic acid conjugated with ethanolamine or glycerol and are able to bind to CB1 and CB2 receptors although, with differences in affinities and activation efficacies (Howlett, 2002). During the last few years, several other bioactive lipid mediators have described they appear to be active, through CB1 and CB2 receptors and confer specific pharmacological effects in vivo. Specifically, the compounds are 2-arachidonoyl-glyceryl-ether (anoladin ether) o-arachidonoyl-ethanolamine (virodhamine), N-arachidonoyl-dopamine and possibly oleamide (Hanus et al., 2001; Porter and Felder, 2001; Huang et al., 2002; Leggett et al., 2004) (Fig. 2).

Cannabinoid receptors, endocannabinoids and the whole apparatus appointed of their synthesis and degradation represent the elements of a novel endogenous signalling system (the endocannabinoid system) which is implicated in a overabundance of physiological functions (Piomelli, 2003; De Petrocellis et al., 2004). During the last few years a notable quantity of data has been reported to understand the biological roles of this system in more detail.

In general, endocannabinoid system serves several functions under physiological conditions. In the CNS, endocannabinoids intervene in the regulation of cognitive functions and emotions in neuronal circuits of the cortex, hippocampus and amygdale and to the reinforcement of substances of abuse in the mesolimbic system (Gerdedman et al., 2003).

**RESULTS AND DISCUSSION**

Cannabinoids for mental and motor dysfuctions in neurodegenerative diseases

Cannabinoids for Alzheimer disease: AD is the most common neurodegenerative disease in Western Europe and an important public health problem as the number of cases is increasing with aging of the population. It
manifests with progressive decline in memory and intellectual abilities, impoverishment of language, disorientation and behavioral skills. The characteristic neuropathological aspects of AD are Senile Plaques (SP), Neurofibrillary Tangles (NFT) and amyloid angiopathy. Brain lesions associated with AD such as NFT and SP are characterized by the presence of a broad spectrum of inflammatory mediators produced by cells residing in the brain, including neurons. Although, of secondary importance compared to the fundamental cause that determines the presence of tangles and plaques there is strong evidence that inflammation exacerbates the neuronal cell loss. Consequently, AD risk is substantially influenced by several polymorphisms in the promoter region of genes and other non-coding regions for inflammatory mediators. Alleles that support the increased expression of inflammatory mediators or alleles that favour the reduced expression of anti-inflammatory mediators are more frequent in patients with AD compared to controls. The polymorphisms are fairly common in the general population, so, there is a strong probability that everyone will inherit one or more high risk alleles (Licastro and Chiappelli, 2003; Vincenzo et al., 2011).

AD also is characterized by enhanced beta-amyloid peptide (β) deposition along with glial activation in senile plaques, selective neuronal loss and cognitive deficits. The role of cannabinoid receptors in AD and their possible protective effects after β-A treatment was studied by Ramírez et al. (2005). This study showed that senile plaques in AD patients express CB1 and CB2 cannabinoid receptors as well as markers of microglial activation. Furthermore while high level of CB1-positive neurons are present in control cases they are greatly reduced in areas of microglial activation (Ramírez et al., 2005). Also, G-protein coupling and CB1 receptor protein expression are markedly decreased in AD brains whereas protein nitration is increased (Ramírez et al., 2005). Cannabinoids (HU-210, WIN 55,212-2 and JWH-133) prevent both betaA-induced microglial activation, cognitive impairment and loss of neuronal markers and abrogate microglia-mediated neurotoxicity after β addition to, rat cortical cocultures (Ramírez et al., 2005). These results indicate that cannabinoid receptors are involved in the pathology of AD and that they may control the neurodegenerative process occurring in the disease.

The neuroprotective actions of CBD in AD was also studied by Iuvone et al. (2004) by evaluating the effect of cannabidiol, a major non-psychoactive component of the marijuana plant (Cannabis sativa) on β-amyloid peptide-induced toxicity in cultured rat Pheocromocytoma PC12 cells. β-amyloid peptide induced a strong reduction of cell survival as well as an increased Reactive Oxygen Species (ROS) production, lipid peroxidation, caspase 3 (a key enzyme in the apoptosis cell-signalling cascade) appearance, DNA fragmentation and intracellular calcium was observed. Treatment of the cells with cannabidiol, prior to β-amyloid peptide exposure, significantly elevated cell survival while it decreased ROS production, lipid peroxidation, caspase 3 levels, DNA fragmentation and intracellular calcium. These results indicate that cannabidiol exerts a neuroprotective effects against β-amyloid peptide toxicity suggesting the an possible involvement of cannabidiol in the signalling pathway for this neuroprotection. This hypothesis was supported by a further study where CBD inhibited both nitrite production and Nitric Oxide Synthase (iNOS) protein expression induced by β-A (Esposito et al., 2006a, b). These results of in vitro studies were confirmed in vivo with a mouse model of AD-related neuroinflammation. Mice were inoculated with human β-A into the right dorsal hippocampus andtreated daily with vehicle or CBD (2.5 or 10 mg kg, i.p.) for 7 days. In contrast to vehicle, CBD dose-dependent significantly inhibited mRNA for glial fibrillary acidic protein and the protein expression in β-A injected animals. Moreover, under the same experimental conditions, CBD impaired iNOS and IL-1β protein expression and the related NO and IL-1β release (Esposito et al., 2007). The possibility of CBD inhibiting β-A-induced neurodegeneration is very promising to AD prevention.

Cannabinoids for parkinson disease: While AD is the most prevalent neurological disorder in the aged population, PD is the second most common neurodegenerative disease. Several studies indicate the presence of inflammatory mediators (including TNF-α, IL-1β, IL-6 and interferon-γ (IFN-γ)) in the Cerebrospinal Fluid (CSF) of patients with PD as well as in the post-mortem substantia nigra pars compacta in PD patient brains (Vincenzo et al., 2011; Banati et al., 1998).

There is an increase in the levels of proinflammatory cytokines in the CSF and nigrostriatal regions of PD brains. Furthermore, large numbers of reactive microglia are found in the substantia nigra of PD patients. These may chronically produce ROS, resulting in depletion of antioxidant stores that may jeopardize mitochondrial activity. Since, aerobic respiration in mitochondria is responsible for most of the ROS produced in cells, abnormalities in these organelles may exacerbate oxidative stress (Vincenzo et al., 2011; Banati et al., 1998).

A recent study (Moller, 2010) showed that CBD may induce neuroprotection in animal models of Parkinson’s Disease (PD). Daily administration of CBD for 2 weeks reduced significantly the toxicity induced by injection of
6-hydroxydopamine into the medial forebrain bundle (Moller, 2010). In this model of PD, CBD led to an up-regulation of mRNA levels of Cu/Zn-superoxide dismutase, a key enzyme in endogenous defense against oxidative stress. The conclusion was that CBD can provide neuroprotection against the progressive degeneration of nigrostriatal dopaminergic neurons that occur in PD (Garcia-Arencibia et al., 2007). This study was confirmed by another study showing that CBD reduced the striatal atrophy caused by 3-nitropropionic acid, in vivo, through mechanisms independent of the activation of cannabinoid, vanilloid TRPV1 and adenosine A$_{2A}$ receptors (Sagredo et al., 2007). Also, the neuroprotective action of CBD in the human basal ganglia was supported by the strong relationship between N-acetylaspartate/total creatine ratio and CBD in the putamen/globus pallidum found in recreational Cannabis users. This could reflect an enhancement of neuronal and axonal integrity in these regions by CBD (Hermann et al., 2007).

Given the above preclinical evidences for the first time, a clinical study evaluated the efficacy, tolerability and safety of CBD in PD patients (Frank-Cannon et al., 2009). In an open-label pilot study, 6 consecutive outpatients with the PD diagnosis received a flexible-dose regimen of CBD administration (starting with an oral dose of 150 mg/day) for 4 weeks in addition to their usual therapy. The PD psychotic symptoms significantly were reduced along the CBD treatment and the scale used to follow up the PD course exhibited a significant decrease of the total score. These preliminary data suggest that CBD may have a beneficial action in PD (Iuvone et al., 2004).

**Cannabinoids for amyotrophic lateral sclerosis:** ALS is a progressive neurodegenerative disease in which motor neurons in the brain and spinal cord are selectively destroyed. Usually, the disease manifests itself during the mid-50s, although, there are rare cases of early-onset ALS. The symptoms of the disease are muscle wasting and atrophy leading to eventual paralysis and death (Vincenzo et al., 2011; Nguyen et al., 2001). ALS is typically fatal within 5 years of diagnosis due to a progressive, generalized paralysis that eventually affects the muscles of respiration, causing respiratory failure (Vincenzo et al., 2011; Nguyen et al., 2001). Areas where degenerating motor neurons are present in both ALS patients and mice models are marked by the presence of cytokines and immune cells, including T cells, activated microglia and astrocytes (Vincenzo et al., 2011; Nguyen et al., 2001).

Although, a generalized neuroinflammatory response may be driving progressive loss of motor neurons, not all inflammatory mediators have been strongly implicated in ALS. For instance, IL-1β may not be critical to ALS pathogenesis as genetic deletion of IL-1β does not change the lifespan or rate of motor neurodegeneration in mutant SOD-1 mice (Vincenzo et al., 2011; Hancock et al., 1998). Currently, no effective pharmacological agents exist for the treatment of this devastating disease and neuroinflammation may accelerate the progression of ALS. However, cannabinoids have been reported to be able to reduce the progression of ALS neuroinflammatory diseases through both CB1 and CB2 receptors (Shoemaker et al., 2007). The involvement of CB receptors in the development of ALS neuroinflammation was demonstrated by using an ALS animal model; G93A-SOD1 mutant mice cannabinoids (Shoemaker et al., 2007). The symptomatic mice showed elevated endogenous cannabinoids and the treatment with non-selective cannabinoid partial agonists prior to or upon, symptom appearance minimally delays disease onset and prolongs survival through undefined mechanisms (Shoemaker et al., 2007). Furthermore, in this ALS animal model, CB2 receptors which normally exist primarily in the periphery are dramatically up-regulated in inflamed neural tissues associated with ALS disorders (Shoemaker et al., 2007). The efficacy of the selective CB2 agonist AM-1241 to increase the survival interval by 56% suggest that CB2 agonists may slow motor neuron degeneration and preserve motor function and represent a novel therapeutic modality for treatment of ALS (Shoemaker et al., 2007).

**Cannabinoids for multiple sclerosis:** MS is a chronic condition in which the immune system attacks the axonal myelin sheaths. The site of inflammatory damage is scarred, thus, the disease name is derived from sclerosis meaning “scar” in Latin (Vincenzo et al., 2011; Nguyen et al., 2001). Since, these loci of injury can occur anywhere in the brain and spinal cord, the symptoms of the disease are usually diverse in different patients. These include fatigue, numbness, vision abnormalities, incontinence, muscle weakness and paralysis.

MS is an autoimmune condition where foci of chronic inflammation lead to compromise of oligodendrocytes and destruction of the myelin sheath. This is followed by axonal damage and consequent neuronal degeneration. Inflammation and neurodegeneration do not occur simultaneously and axonal damage and brain atrophy may follow months after an acute innate immune response (Vincenzo et al., 2011; Nguyen et al., 2001). At today, numerous drugs target the immune system to reduce the
progression of MS but they are only moderately effective and the treatment of MS remains mostly symptomatic and far from satisfactory (Killestein et al., 2004).

Cannabis had been used in ancient Greece, Rome, China and India for relieving muscle cramps, spasm and pain (Mechoulam, 1986a, b; Mechoulam et al., 1998; Mechoulam and Hanus, 2000) and its therapeutic application in MS is a topic of recent lively debate (Grundy, 2002; Fertwee, 2002; Baker and Pryce, 2003; Croxford, 2003; Killestein et al., 2004; Sirven and Berg, 2004; Jackson et al., 2005a, b; Pryce and Baker, 2005; Robson, 2005; Smith, 2005, Lyman et al., 1989). The effects of THC in MS was studied by using an Experimental Autoimmune Encephalomyelitis (EAE) in rats (Lyman et al., 1989). In this MS experimental model, THC treatment was able both to reduce neuroinflammation and to improve neurological outcome as well as survival compared with placebo. Also, ∆9-THC, a less psychotropic and more stable analog of THC and the nonpsychotropic dexamabinal were able to reduce the severity and incidence of neurological deficits in rats with EAE (Wirguin et al., 1994; Achiron et al., 2000; Berrendero et al., 2001). The efficacy of THC was also, confirmed with a mouse model of chronic relapsing EAE (Baker et al., 2000) indicating a tonic control of muscle tone by the endocannabinoid system in EAE (Baker et al., 2000; Ligresti et al., 2006). The use of CB1-deficient mice which tolerated inflammatory and excitotoxic insults poorly and developed substantial neurodegeneration after the induction of EAE further confirmed the above studies (Pryce et al., 2003; Jackson et al., 2005a, b; Ni et al., 2004; Witting et al., 2006).

Theiler’s murine encephalomyelitis virus-induced demyelinating disease is another murine model of MS. In this MS Model, the treatment with cannabinoids reduced the progression of symptoms, down-regulated delayed-type hypersensitivity reactions and interferon-γ production and inhibited the expression of proinflammatory cytokines in the CNS (Croxford and Miller, 2003; Arevalo-Martin et al., 2003; Mestre et al., 2005; Ortega-Gutierrez et al., 2005).

Given the above the animal data, cannabinoids have shown promise in the treatment of MS in humans. A possible underlying mechanism is suggested by a recent study in which the endocannabinoid system was found to be highly activated during CNS inflammation in MS patients and to protect neurons from inflammatory damage by activating a negative feedback loop in microglial cells via, CB1/2-mediated epigenetic regulation of mitogen-activated protein kinase phosphatase 1 expression (Eljashewitsch et al., 2006).

Anecdotal reports showing the efficacy of marijuana smoking in relieving symptoms of MS (Grinspoon and Bakalar, 1993, 1998) were supported by the results of early open or single-blind observations with orally given THC or smoked marijuana, involving small numbers of patients (Dunn and Davis, 1974; Petro, 1980; Petro and Ellenberger, 1981; Clifford, 1983; Meineck et al., 1989; Breneisen et al., 1996; Schon et al., 1999). The results of this study showed a significant improvement in spasticity, mobility, tremor, dysthymia, mood and bladder control. In a double-blind crossover study of a single MS patient, nabinal treatment improved muscle spasms, nocturia and general well-being (Martyn et al., 1995). Although, these encouraging reports have triggered numerous larger, population-based clinical trials of Cannabis-based medicines in MS, mixed results have been reported (Greenberg et al., 1994; Consroe et al., 1997; Killestein et al., 2002; Thompson and Baker, 2002).

A large multicenter study involving 33 clinical centers and 660 MS patients in the United Kingdom and United States and supported by the UK Medical Council aimed to explore the effects of Cannabis extract (Cannador) or synthetic THC (Marinol) versus placebo on spasticity, pain, tremor, bladder function and cognitive function Cannabinoids in Multiple Sclerosis (CAMS) study (Zajicek et al., 2003). After 15 weeks of treatment with Marinol or Cannador there was significant improvements in patient-reported spasticity, pain and sleep quality as well as a reduction in hospital admissions for relapse in the 2 active treatment groups (Zajicek et al., 2003). However, no benefits were observed in Ashworth score, tremor, irritability, depression or tiredness and adverse side effects were generally minor and similar to those with placebo (Zajicek et al., 2003; Fox et al., 2004). The improvements in spasm frequency and mobility by THC plus CBD in MS patients were confirmed in further studies of similar design (Vaney et al., 2004; Wade et al., 2003, 2004; Smith, 2004; Russo and Guy, 2006; Russo, 2008).

In conclusion, controlled clinical trials with cannabinoids have demonstrated their efficacy in eliciting symptomatic improvements in MS patients. These results suggest that there is place for the use of Cannabis in the treatment of MS which should be confirmed in further larger-scale clinical trials.

Phytocannabinoids for Huntington disease: While neuroinflammation has been targeted in many neurodegenerative diseases ranging from AD-ALS-PD it has not received much attention from the HD community. However, several published trials while not having neuroinflammation per se in mind, might have also targeted this process (Moller, 2010).
Several studies indicate that inflammation appears in the CNS during the progression of HD and HD-like pathologies. Several brain regions from HD patients and controls revealed increased gliosis and expression of inflammation-related genes including glial fibrillary acidic protein and complement proteins. Increases were most pronounced in the caudate putamen where brain pathology is most severe in HD patients (Moller, 2010). Additionally, increased levels of pro-inflammatory cytokines involved in the innate immune response such as IL-6 were detected in HD patients as well as an altered immune profile before onset of clinical HD symptoms, suggesting that striatal and cortical neurodegeneration could be exacerbated by inflammation (Moller, 2010). Thus, it is clear that also, HD is related to the neuroinflammation process such as disruption of normal microglial functions and neuronal distress. This neuroinflammation may contribute to the death of additional neurons and once better understood, targeted intervention with neuroinflammatory processes, active or reactive, could be a valuable tool for developing new therapeutic approaches (Moller, 2010).

Several studies have reported changes in CB1 receptor levels and CB1 receptor activity in HD and the findings from such studies suggest a role for the endocannabinoid system in the pathophysiology of these and other neurological diseases (Fernandez-Ruiz, 2009; Glass et al., 2000; Lastres-Becker et al., 2001).

Animal models of HD as well as post-mortem studies carried out in HD patients suggest that CB1 receptors of basal ganglia are downregulated and/or desensitized as a result of the expression of the mutant Huntingtin protein and that this occurs early in the course of the disease and prior to the appearance of overt clinical symptoms (Glass et al., 2000; Lastres-Becker et al., 2001; Denovan Wright and Robertson, 2000; Lastres-Becker et al., 2002; Naver et al., 2003; McCaw et al., 2004; Centonze et al., 2005; Pazos et al., 2008; Dowie et al., 2009; Blazquez et al., 2010; Casteels et al., 2011; Mievis et al., 2011). A recent in vivo PET study of HD patients supports these findings, indicating a significant reduction in CB1 receptor availability throughout the gray matter of the cerebral cortex, cerebellum, and brainstem of HD patients even in early stages of the disease (Van Laere et al., 2010). Also, pre-clinical and post-mortem studies in HD patients indicate an inverse relationship between the decrease in CB1 receptor levels and the increase in CB2 receptor levels in glial elements, astrocytes and reactive microglial cells (Palazuelos et al., 2009). Further clinical and pre-clinical evidence evidence strongly support that changes in the endocannabinoid system are tightly linked to the pathophysiology of HD (Dowie et al., 2009, 2010; Blazquez et al., 2010; Casteels et al., 2011; Mievis et al., 2011; Van Laere et al., 2010; Palazuelos et al., 2009; Consroe et al., 1991; Curtis et al., 2009; Muller-Vahl et al., 1999; Curtis and Rickards, 2006).

The strong relationship between cannabinoids and HD was further confirmed by a study using an HD animal model (Blazquez et al., 2011). The results of this study confirmed the CB1 receptors reduction in the basal ganglia leading to increases in Huntington’s-like symptom and the lower levels of BDNF in mice with a lack of CB1 receptors may further contribute to HD development. Indeed, BDNF replacement is believed to be a possible therapeutic for HD and has been shown to decrease excitotoxicity and attenuate motor dysfunction and cell loss in animal models of HD (Blazquez et al., 2011).

CONCLUSION

In conclusion, the present study showed a strong link between cannabinoids and neurodegenerative diseases. Neuroprotective activities of endocannabinoids appear to be mainly CB1-mediated thus promising avenues for the therapeutic targeting of different aspects of neurodegenerative diseases by stimulating a self-protective endogenous system of the brain and by counteracting oxidative stress.

Increased research on cannabinoid medicine and modulation of the endocannabinoid system in relation to neurodegeneration has the potential to lead to novel therapies which may help to prevent progression and potentially initiation of these diseases.
