Abstract: Many studies have suggested that oils high in saturated fatty acids are responsible for the cholesterol-raising effect of saturated fat. The aim of this study was to compare the effect of palm oil (rich in saturated fatty acid) and egusi melon oil (rich in unsaturated fatty acids) on serum and liver lipids and their antioxidant status. Lipid profiles, Malondialdehyde (MDA) levels and activities of Glutathione Peroxidase (GSH-Px) and Glutathione Reductase (GSSG-Rx) were determined in serum and liver of rats fed a high cholesterol diet for 6 weeks. Palm oil and egusi melon fed rats exhibited improved serum and liver lipid profiles and had a more significant reduction in serum and liver MDA levels as compared to control rats. Similarly, GSH-Px and GSSG-Rx activities were significantly higher in rats fed palm oil and egusi melon oil compared to control. It could thus be concluded base on these findings that palm oil and egusi melon improve serum and liver lipid profile in rats fed a high fat diet their consumption could thus offer protection against lipid-related disorders.

Key words: Palm oil, egusi melon oil, saturated fatty acids, antioxidant, cholesterol-raising effect, serum

INTRODUCTION

It is clearly established that long term consumption of a high fat diet accelerates the development of Coronary Heart Disease (CHD). Therapeutic agents which control the levels of serum cholesterol have proven to be effective in the treatment of CHD (Bays and Stein, 2003; Linsel-Nitschke and Tall, 2005). While agents exist that can modulate circulating levels of cholesterol carrying lipoproteins by inhibiting cholesterol synthesis, these agents have little or no effect on the intestinal absorption of cholesterol.

Dietary cholesterol can increase the level of serum cholesterol to levels which can place an individual at increased risk for the development or exacerbation of atherosclerosis (Onyeneke *et al.*, 2007; Oluba *et al.*, 2008a). CHD increases dramatically as the plasma concentration of LDL cholesterol increases (Berg *et al.*, 1986). Consequently, development of methods for lowering LDL cholesterol levels has become a major focus of medical research.

The approach of reducing dietary cholesterol suffers from two limitations. The first is that cholesterol is present in all animal fats and many people are unwilling to scarify their preferred diet. The second is that the liver and other tissues synthesize cholesterol de novo if the dietary supply is inadequate. Palm Oil (PO) obtained from a

tropical plant *Elaeis guineensis* represents the second largest volume of vegetable oil produced in the world. It is rich in saturated fatty acids, antioxidant and vitamins and is widely used as oil in diet. Earlier study by Oluba *et al.* (2008b) showed that PO is more hypocholesterolemic than soybean oil when both are fed as a supplement (5% v/w) to a high fat diet in rats. On the other hand Egusi Melon Oil (EMO) obtained from the seeds of *Citrullus lanatus* and used as a common component of daily meals in West Africa is predominantly composed of unsaturated fatty acids (percentage composition by weight of oil: lauric, 0.21; myristic, 0.78; palmitic, 13.45; stearic, 13.71; oleic, 14.50; linoleic, 56.94 and linolenic, 0.46) (Oluba *et al.*, 2008c). Based on previous these findings we sought to investigate whether PO (a saturated fatty acid source) and EMO (an unsaturated fatty acid rich source) have the same, similar or different effect on serum and tissue lipid profiles and their antioxidant activity in rats fed a high fat diet.

MATERIALS AND METHODS

Collection and preparation of egusi melon seeds sample:

Egusi melon seeds used for this study were obtained from a local market in Iwaro-Oka Akoko, Ondo State, Nigeria and were identified as *Citrullus lanatus* (egusi melon) by a taxonomist in the Department of Crop Science, Faculty

of Agriculture, University of Benin, Nigeria. The seeds were screened to remove bad ones, shelled manually and further screened. The seeds were then dried to constant weight in an oven at 70°C, ground using mechanical grinder put in air-tight containers and stored in desiccators for further analysis, some of the seeds was subsequently deposited at the herbarium of the faculty.

Oil extraction: Oil from the seeds of egusi melon was extracted by continuous extraction in Soxhlet apparatus (Cehmglass) for 8 h using petroleum ether (60-80°C boiling range) as solvent according to the method of AOAC (1980). At the end of the extraction the extraction solvent was evaporated in a rotary evaporator (Cehmglass). The extracted oil was used for feed formulation and the remaining stored in light proof, airtight and moisture proof container at -4°C.

Palm oil sample: Palm oil sample used for the study was obtained from Okitipupa Oil Palm Mill, Okitipupa, Ondo state (Nigeria). The oil was stored in light proof, airtight and moisture-proof container at -4°C.

Experimental animals: Male Wistar rats 6 weeks old and having a mean weight of 72.4±4.8 g were obtained from the Nigerian Institute of Medical Research, Lagos and housed individually in stainless steel cages with raised wire floor in an environment of 24-25°C, 50-60% relative humidity and a 12 h light dark cycle. Rats were acclimated to individual cages for 1 week before the diet treatment. During the acclimatization period, the rats were provided unlimited access to a commercial rat chow (Guinea Feed Ltd, Nigeria) and water *ad libitum*. All experimental protocols complied with NIH guidelines (National Research Council, 1985).

Diets: At the end of the 1st week, animals were assigned by weight into of three groups (n = 10/group) and assigned to the experimental diet for 6 weeks. The diet groups included Control (CO), Palm Oil (PO) and Egusi Melon Oil (EMO). The experimental diets were prepared according to the recommendations of the American Institute of Nutrition (AIN) and contained (% weight) casein 20, fat 10, vitamin mixture (AIN-76) 3.5, choline bitartrate (BDH, England) 0.2, DL-methionine (Sigma, England) 0.3, corn starch 15 and sucrose to 100%. In addition fresh palm oil (5%) and egusi melon oil (5%) were added and mixed with PO and EMO diet, respectively.

Experimental design: Before the commencement of the feeding experiment animals were deprived food overnight but allowed access to water *ad libitum*. About 5 rats from

each group were then sacrificed and blood and liver samples were taken to establish the baseline levels of the studied parameters. At the end of the diet treatment the remaining animals in each group were fasted overnight and sacrificed by decapitation. Animals were allowed free access to food and water for the duration of the study. Diet consumption and body weight were measured weekly, correcting for food spillage.

Serum preparation: At pre and post-diet treatment period about 2 mL blood samples were collected from each animal by cardiac puncture into plain tubes. The blood was allowed to clot at room temperature for 1 h and then centrifuged at 3000 g for 10 min the serum was separated into plain tubes and frozen at -20°C until analysis.

Liver lipid: Total lipids were extracted from liver according to Folch *et al.* (1957).

Cytosolic and microsomal fractions: Liver cytosolic and microsomal fractions were prepared by the method of Speir and Wattenberg (1975). Briefly, rat liver was immediately removed, washed in ice cold 1.15% KCl solution, blotted, weighed, cut into small pieces in 1.15% KCl at a volume of 3 mL of KCl g⁻¹ liver and homogenized in 4 volumes of the homogenizing buffer (pH 7.4) using a Potterelvegin homogenizer. The homogenate was centrifuged at 900 g at 4°C for 20 min in a Sorvall RC-5B superspeed centrifuge. The supernatant was pipetted into a clean centrifuge tube and centrifuged further at 105,000 g at 4°C in a Beckman L5- 50B ultracentrifuge for 45 min. The cytosol was used for GSH-Px and GSSG-Rx activities.

Lipid assays: Total Cholesterol (TC), HDL-cholesterol and Triacylglycerol (TAG) were quantified using enzymatic kits (Randox Laboratories, San Francisco, USA) methods according to the manufacturers instructions. Non HDL-cholesterol was calculated Friedwald formula.

Estimation of lipid peroxidation products: Lipid peroxidation was estimated in liver by assessing Malondialdehyde (MDA) levels using the Thiobarbituric Acid Reactive Substances (TBARS) methods of Varshney and Kale (1990).

Enzyme assay: Glutathione Peroxidase (GSH-Px) activity was measured according to the method described by Rotruck *et al.* (1973). Glutathione Reductase (GSSG-Rx) activity was measure by the method of Racker (1955) with slight modifications. The assay mixture consisted of 0.1 M phosphate buffer (pH 7.6), 0.1 mM NADPH, 0.5 mM

EDTA, 1 mM GSSG and cytosol in a final volume of 1.0 mL. The enzyme activity quantitated at 29°C by measuring the disappearance of NADPH at 340 nm. Specific activity for GSSG-Rx was defined as the oxidation of 1 µmol of NADPH per min per mg protein. Protein estimation was conducted by Lowry *et al.* (1951) method.

Statistical analysis: Data are mean±SEM of five determinations. Statistical analysis was by Analysis Of Variance (ANOVA) and Duncan's Multiple Range Tests (DMRT) using SPSS 10.0. $p < 0.05$ than control was considered significant.

RESULTS AND DISCUSSION

No significant differences in food intake (23.1±3.2 g day⁻¹) among the three diet groups during the study. At the end of the experiment, rats fed PO and EMO diets gained less weight than rats fed control diet however, rats fed PO diet gained less weight than those fed EMO diet ($p < 0.05$) (Table 1). The difference in weight gain could be attributed to the low total body fat content in the group fed PO in comparison with the group fed EMO (Table 1).

Serum lipids: Serum TC concentrations was about 30 and 20% significantly lower ($p < 0.001$) in the groups fed PO and EMO, respectively than in the CO group. Although, rats fed PO had higher reduction than rats fed EMO diet in serum TC, the difference was not significant ($p > 0.1$) (Table 2). Serum TG concentrations were about 30%

significantly lower in both PO and EMO fed rats compared to CO group. No significant difference ($p > 0.1$) was observed in serum TG levels between PO and EMO groups (Table 2). No significant differences ($p > 0.1$) in serum HDL-C were detected among the three groups at the end of the study. However, serum nHDL-C was significantly lower ($p < 0.001$) in both PO and EMO than in the CO group. A non-significant ($p > 0.1$) lower concentration in serum nHDL-C was also observed in PO compared to EMO group (Table 3).

Liver lipids: Analysis of liver lipid composition showed that animals in PO and EMO had significantly lower ($p < 0.001$) levels of TC compared to those in CO group at the end of the study. Though TC concentration was lower in PO group than in EMO group the decrease is not significant ($p > 0.1$) (Table 4). Hepatic TAG concentrations were significantly ($p < 0.001$) reduced in both PO and EMO rats compared to rats in CO group. The decreased level

CO: Control group; PO: Palm Oil group; EMO: Egusi Melon group; MDA: Malondildehyde; GSH-Px: Glutathione Peroxidase; GSSG-Rx: Glutathione Reductase. *Statistically different (p<0.05) from Control (CO)

observed in liver TAG in PO rats compared to EMO rats was not significant (p>0.1) (Table 4). Lipoprotein fraction analysis of the liver revealed a significant increase in HDL-C in PO group compared to CO group and a non-significant increase (p>0.1) in EMO group compared to CO group (Table 5). The nHDL-C levels were significantly reduced in both PO and EMO groups compared to CO group. The nHDL-C was also significantly reduced (p<0.001) in PO group compared to EMO group (Table 5).

Antioxidant status: Serum concentration of MDA was significantly reduced in both PO and EMO groups compared to CO group. A significantly lower value was also observed when MDA level in PO group was compared to EMO group (Table 6). However, serum activities of GSH-Px and GSSG-Rx were significantly elevated in both PO and EMO groups compared to CO group. A significantly higher difference was also observed when activities of both enzymes in PO rats were compared to those of EMO animals Table 7. Liver concentrations of MDA were significantly lower in both PO and EMO groups when compared to CO group. However, liver activities of GSH-Px and GSSG-Rx were significantly elevated in both PO and EMO groups compared to CO group. A non-significantly (p<0.1) higher difference was also observed when activities of both enzymes in PO rats were compared to those of EMO animals Table 7). Body weight gain differed despite the similar cumulative energy intake throughout the study in the three groups. The difference in weight gain could be

attributed to the low total body fat content in the group fed PO in comparison with the group fed EMO (Table 2-5). Cholesterol feeding has often been used to elevate serum cholesterol concentration in studying the etiology of hypercholesterolemia related metabolic disturbances such as atherosclerosis. In this study, the elevated serum and liver TC and TG concentrations following consumption of a high cholesterolemic control diet were similar to the responses reported in rats fed diets with similar amounts of cholesterol (Onyeneke *et al.*, 2007; Oluba *et al.*, 2008a). It is observed from this study that palm oil, a saturated fatty acid rich oil, better improves serum lipid profile than egusi melon oil. According to a report by Oluba *et al.* (2008c), egusi melon oil like soybean oil is predominantly composed of unsaturated fatty acids especially linoleic acid.

The results of this study invalidate the general misconception that oils rich in saturated fatty acid increase serum cholesterol compared to those rich in unsaturated fatty acids. Data generated in this study are in accordance with the findings of Oluba *et al.* (2008b) that palm oil lowers serum TC and TG compared to soybean oil when both are fed as supplements to a high cholesterol diet in rats. Similarly, Scholtz *et al.* (2004) in a separate study reported that palm oil lowers serum TC and nHDL-C concentrations than coconut oil.

Another interesting finding from this study is the effect of palm oil and egusi melon oil on both serum and liver antioxidant status. Cholesterol inclusion in the diet has been reported to decrease the circulating levels of insulin and serum glutathione (Scholtz *et al.*, 2004) thus

predisposes to tissue lipid peroxidation. The elevated concentrations of tissue TC, TG and nHDL-C following a high cholesterol diet presumably could increase the susceptibility of tissues to lipid peroxidation unless adequate amounts of antioxidants are present. Thus, the observed decreases in serum and liver MDA concentrations and increases in GSH-Px and GSSG-Rx activity (which are important lipid peroxide decomposing enzymes in rats) could be attributed to the hypocholesterolemic effect of these oils in the serum and liver.

Several mechanisms have been advanced to explain the unexpected hypocholesterolemic action of palm oil. Of importance is its rich content of the antioxidant, tocotrienols. Studies have confirmed that tocotrienols inhibit cholesterol synthesis *in vivo* (Karaji-Bani *et al.*, 2006) thus enhancing the receptor-mediated transport of serum cholesterol to the liver. Tocotrienols could also participate in clearance of lipid peroxides which may be generated as a result of cholesterol feeding. On the other hand, the effect of egusi melon (though has not received much attention in terms of its nutritional potential) on serum cholesterol may be attributed to its rich content of essential fatty acids.

CONCLUSION

In conclusion, the results of this study showed that palm oil and egusi melon oil improve serum and liver lipid profiles and offer better protection against resultant lipid peroxides from consumption of high fat diet.
