

Tsunami Deposit Study Using 2D ERI Technique in Thoothukudi Shoreline, Tamil Nadu, India

A. Antony Ravindran
 Department of Geology and Geophysics Research Lab,
 Manonmaniam Sundaranar University, Thoothukudi, India

Abstract: The aim of the study is about beaches in the study area acts like a sponge but the groundwater along the beach is very dynamic. The flow direction of the beach groundwater is mainly governed by the physical and geological characteristics of the beaches as well as the waves and tide conditions in the sea. The Indian Ocean Tsunami 2004 was affected and sediment deposited in the Thoothukudi shoreline. Through the 2D Electrical Resistivity Imaging (ERI) Technique, an attempt is made to understand the interface zone of the seawater intrusion and the land groundwater along the beach groundwater table and Tsunami deposits in the Thoothukudi shoreline. The profiles survey were carried out using the help of equipment like CRM-500, Multicore cable, electrodes and Res 2DINV Software. The measuring profiles are predetermined as a interval of electrodes in m and cm scales. From four profiles study is to determine the salt water and clay tsunami deposit range of apparent resistivity from $1-5 \Omega \text{ m}^{-1}$, sandy $10-100 \Omega \text{ m}^{-1}$.

Key words: Tsunami, sediments, 2D ERI, Thoothukudi shoreline, resistivity, India

INTRODUCTION

The Tsunamigenic earthquake of December 26th, 2004 happened on the interface of the India and Burma plates and was caused by the release of stresses that develop as the Indian plate subducts beneath the overriding Purma plate. The coastal area of Gulf of mannar region was affected due to tsunami. The geological and

for paleoseismological approach in search of ancient tsunami deposits and geomorphic features which were the direct diagnostic criteria of the ancient earthquake (Keating *et al.*, 2004). Geo-electrical studies for delineating ground-water contamination due to salt-water intrusion in the delta (Ebraheem *et al.*, 1997; Zohdy *et al.*, 1993). Tsunamis have the potential to deposit sand farther inland or at a higher elevation than storms (Dawson and

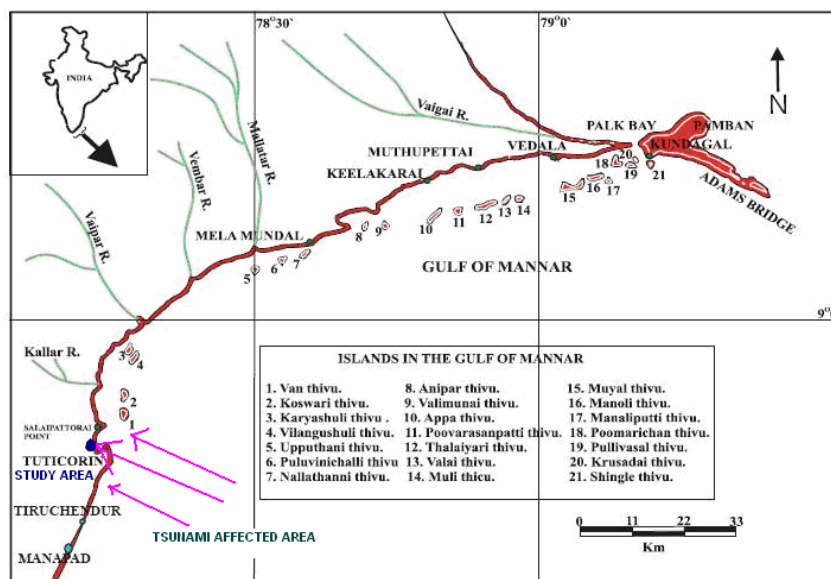

Fig. 1: Location map of the study area

Shi, 2000; Dawson *et al.*, 1988). The use of 2 D resistivity imaging (electric tomography) identifies the tsunami deposits in the Thoothukudi shoreline (Fig. 1) Thoothukudi district, located along South-East of India. This is one of Pearl city of India and Coastal district of Tamil Nadu state. This is located between 8°19' and 9°20'N latitudes and 77°40' and 78°10'E longitudes. It has a semi arid-tropical climate.

Air temperature data indicate that May to August are the hottest months in district and December to February are coolest months in every year. The mean annual temperature of district is 28.3°C. Mean annual precipitation of rainfall is 675.71 mm. Major rainfall is received during the Northeast monsoon period. Maximum rainfall is in month of November.

Geology of the study area: The archean formation of Thoothukudi district include quartzite, garnetiferous biotite gneiss, charnockite, calc granulite and pink granite. The general trend of the Quartzite is NS to NE-SW with gently dipping towards East to Southeast. A group of fine grained marine calcareous sandstone and limestone and gritty sandstone intercalated with pebble bed probably referable to mio-pliocene age lie over the archeans. Dunes of white sand and red Teri sands of recent origin parallel to the coast are found (Ravindran *et al.*, 2011). Since Thoothukudi is one of the important coastal district of Tamil Nadu state. The coastal features are occurring such as bays, lagoons, estuaries, cliffs, dunes, backshore width, beach width, wave cut features etc.

MATERIALS AND METHODS

The tsunamigenic deposits were studied using the 2D electrical resistivity imaging study to parallel to shoreline. It is one of the powerful tools to identify sedimentary deposits of the study area. The 2D Electrical Resistivity Imaging Technique is a fast and cost effective technique which covers both vertical and horizontal changes in the surface and the subsurface of the geological formations of the study area.

To determine the true subsurface resistivity, the collected resistivity data are inverted into apparent resistivity data by using Res 2D INV Ver.3.56 software and iterated to calculate a resistivity model section (Ravindran, 2010; Ravindran and Ramanujam, 2012). This approach minimizes the difference between the observed data and the calculated apparent resistivity values. The data were collected using the equipment of Aquameter CRM 500, 48 steel electrodes, 12 Volts battery,

Fig. 2: Tsunamigenic deposits field work data collection using 2D ERI electrode arrangement and open trench technique

multi core cables to a length of 240 m and manually operated switching unit have been used for the data collection. Wenner electrode configuration has been used for 2D electrical resistivity imaging studies. Lateral extension of the spaces can be made by roll on technique. To find out the layer thickness of 10 cm tsunami deposits, 20 cm electrode spacing should be adopted in Wenner configuration.

The tsunami deposit identified at a depth of 80 cm is having lower resistivity than the surrounding beach sands. In the preliminary study, it has been revealed that fine-grained deposits at the 80 cm depth are found more conductive than surrounding beach sands (Fig. 2).

RESULTS AND DISCUSSION

The profile 1 (Fig. 3) trends E-W direction to a length of 8 m. The inversion pseudosection displays the range of resistivity values from 17 $\Omega \text{ m}^{-1}$ indicating that sandstone upto a depth of 7.9 m. The low resistivity zone of pseudosection with the range of resistivity is 0.04-0.51 $\Omega \text{ m}^{-1}$ at a depth of 3.7-7.9 cm indicating the tsunamigenic deposits of the study area.

The profile 2 (Fig. 4) trends SE to NW direction to a length of 100 m. The range of low resistivity zone with 1-5 $\Omega \text{ m}^{-1}$, from the surface of the profile to a depth of 3.8 m indicates a saltwater and tsunami sediment deposited area. The high resistivity values starting from 5-10 $\Omega \text{ m}^{-1}$ extending further downwards upto a depth of 11.9 m in the pseudosection exhibits the distribution of sand and sand dunes of the study area.

The profile 3 (Fig. 5) trends NE to SW direction at a length of 100 m. The tsunami sediment at top of pseudosection are identified with resistivity values from 10.8-5 $\Omega \text{ m}^{-1}$ at a depth of 5.6 m. The sand and sandstone is recognized from the depth of 3.8 m to a depth 11.9 m in

Fig. 6: 2D electrical resistivity imaging pseudosection depicts the distribution of beach sediments and sand dunes in coastal zone of Thoothukudi shoreline profile 4

the pseudosection with the range of resistivity values of 5-10 $\Omega\text{ m}^{-1}$. The profile 4 (Fig. 6) trends SE to NW direction to a length of 100 m distance. The sedimentary rock formation of sand, sandstone is demarcated with the range of resistivity from 5-9 $\Omega\text{ m}^{-1}$. The Tsunami sediments and saltwater intrusion is identified with the range of resistivity value from 1-3 $\Omega\text{ m}^{-1}$ at a depth of 11.9 m.

CONCLUSION

The 2D Electrical Resistivity Imaging Technique is used for identification of tsunamigenic deposits in the coastal region of thoothugudi shoreline. The four 2D profiles have been carried out to assess the subsurface geological and hydrogeological condition to a depth about 11.9 m. 2D pseudosection were constructed for each sites and they show a zones of high resistivity between 5 and 10 $\Omega\text{ m}^{-1}$ which is encircled by a sandstone and sand in dry conditons. The low resistivity zone falls below the 0.8-5 $\Omega\text{ m}^{-1}$ which indicates saltwater and tsunamigenic sediments upto a depth of 5 m from subsurface.

The pseudosections plotted from the data obtained for the study area reveal the saltwater movement of salinity structures due to tsunamigenic earthquake in Indian ocean. The study based on the constructed 2D pseudosection profiles a perfect subsurface tsunami sediments and flow movements of the groundwater were established compared with trenching data at Thoothukudi shoreline, Tamil Nadu, India.

ACKNOWLEDGEMENTS

Researchers express their sincere thanks to Mr. A.P.C.V. Chockalingam, Secretary and Prof. Maragathasundaram, Principal, V.O.C. College, Tuticorin. The helps extended by Dr. N. Ramanujam, Professor and Head, Coastal Disaster Management, Pondicherry University, Andaman.
