ABSTRACT

Geminivirus are a large diverse family of plant viruses that infect a broad variety of plants and cause significant loss to Agricultural crops and ornamental plants in India. The vector white fly is the carrier of these viruses. This review focuses on the current status of *Geminivirus* in India and research related to it. Researches being carried out on *Geminivirus* include their molecular characterization, serological and computational characterization. Many costly measures in controlling the infections and increasing the crop yield have been applied. A cost effective appraise against these viruses is the relevance of RNAi Technology. RNAi is a challenging approach in which an interference RNA molecule put a check halt on the multiplication of *Begomovirus* in plants through its ability to form a Dicer complex.

Key words: *Geminivirus*, agricultural, India, white fly, RNAi, *Begomovirus*, dicer

INTRODUCTION

India has a long history of agriculture farming. Ancient records proved that agriculture is far long being carried out since ages, almost 9000 BC. India is present a developing country. But that day is not so far when India will be a developed country. In making India a developed country maximum contribution to its economy comes from the agriculture sector. According to ICAR Annual Report 2011-2012, in India the growth of agriculture and improving income and livelihood of small holders in agriculture constitute more than 80% of the total farming households, 50% of rural households and 36% of total households in India. Principally agriculture practices in India are seasonal. But with the release of more and more hybrid varieties, crop plants are cultivated throughout the year. Different types of food crops are grown in India such as cereals, pulses, vegetables and fruits (Bhattacharyya and Chakraborty, 2005).

A nearly developed country like India ranking second in farm output worldwide has its major contribution to its economy comes from the agriculture sector. A large number of crop plants are cultivated in India since ages and some of them are unique in their own way. Many have medicinal properties either (Meetei *et al.*, 2012). There are a large number of threats to the agricultural crops grown not in India itself but even across the worldwide (AVRDC, 2012). Large number of pest harms the crops and hinders the production yield (Kataria and Kumar, 2012). But apart from them there are also other microscopic elements that cause a great annual loss to the agriculture sector thus in turn harming the livelihood of the farmers of India and Indian economy. This none other microscopic elements are viruses (CRSP, 2012). Several viruses affect the

crop plants, but the major contribution is from the viruses belonging to the Geminiviridae family. These viruses are transmitted from plant to plant by their main insect host well-known as white fly (*Bemisia tabaci*) (Wang *et al.*, 2012). Other insects such as leafhopper and treehopper are also a causal agent.

This review article depicts the current status of *Geminivirus* in India highlighting various research institute and university where work on Geminiviruses are being carried out and includes a wide range of information mentioning the new disease reports from throughout India. Moreover a list of various Geminiviruses species in India has also been mentioned which gives an idea of new viruses introduced in India and evolution of existing viruses through recombination. To find a cure against these Geminiviruses RNAi technology (Vanitharani *et al.*, 2003; Kurth *et al.*, 2012) is a wonderful tool which employs a check on the devastating nature of Geminiviruses infecting ornamental plants, weeds and crops. Results of these techniques effectively applied for disease management and development of quarantine strategies for handling and transportation of infected plant samples. Thus, it's an approach to bring the research work of various scientists working on Geminiviruses in India at one place in this review article.

GEMINIVIRIDAE FAMILY AND ITS TRANSMISSION VECTORS

In plants 47% infections are caused by viruses. Geminiviridae is the family which consists of maximum number of viruses (Fauquet *et al.*, 2005). General symptoms of diseases caused by *Geminivirus* are curling of leaves, yellowing of veins, yellow mosaic patterns, dwarfing of leaves. Viruses belonging to Geminiviridae family are plant viruses which are obligate intracellular parasites, having no self machinery to replicate themselves (Stanley *et al.*, 2005). It comprises of four genera: *Begomovirus*, *Curtovirus*, *Mastrevirus* and *Topocuvirus*. *Begomovirus* is one the biggest genera of the family (Medina-Ramos *et al.*, 2008). It comprises of around 200 species existing worldwide. *Begomovirus* principally affect the dicotyledonous plant species. These viruses are transmitted by whitefly (Markham *et al.*, 1994).

White fly (*Bemisia tabaci*) belongs to Aleyrodidae family of class Insecta. This fly prevails more in the tropical and subtropical regions of the globe (Sidhu *et al.*, 2009). *Begomovirus* genera comprises of most multifarious genome among other genera's. It has a bipartite genome having two circular DNA designated as DNA A and DNA B. Both DNA A and DNA B range from 2.7 to 3 kb (Hanley-Bowdoin *et al.*, 1999). DNA B is dependent on DNA A for its doings. Moreover in up to date publication an additional circular DNA has been reported as β satellite, also contribute to *Begomovirus* circulation (Briddon *et al.*, 2001) and nanovirus-like DNA satellite molecules (alphasatellites) (Briddon and Stanley, 2006).

Curtovirus another genera of the family consist of 7 species reported so far. The species are Beet curly top Iran virus, Beet curly top virus, Beet mild curly top virus, Beet severe curly top virus, Horseradish curly top virus, Pepper curly top virus and Spinach curly top virus (Bolok Yazdi *et al.*, 2008). *Curtovirus* are transmitted through leaf hopper or treehopper (*Micrutalis malleifera*). They have a monopartite genome. The genome comprises of a circular single stranded DNA molecule ranges up to 3 kb (Balaji *et al.*, 2004). *Mastrevirus* is the second largest genera of this family. It comprises of 14 species as given in ICTV up to date (Brown *et al.*, 2012). Infection of *Mastrevirus* is caused by leaf hopper which is its chiefly host. Leaf hopper belongs to Cicadellidae family. Leaf hopper is a common name applied to any species of Cicadellidae family (Lee *et al.*, 2000). Leaf hopper exists all over the world and do not have a pupae stage while turning into adult from nymph. *Mastrevirus* affect both dicots and monocots plants species. Genome is monopartite and size is up to 2.7 kb. *Topocuvirus* is the smallest genera of Geminiviridae family (Briddon and Markham, 2001). It consists of only one member species reported in the world, known as Tomato

pseudo-curry top virus. It infects the dicotyledonous plant, mainly tomato. It has a monopartite, closed circular, single stranded DNA, about 2.8 kb nucleotides long. The virus is transmitted by treehopper (Hunter *et al.*, 1998).

GENOME ORGANIZATION

According to the below given diagram (Fig. 1) the two circular genome of the *Begomovirus* can be understood easily. DNA A has 6 Open Reading Frames (ORF). They are AC1, AC2, AC3, AC4, AV1 and AV2. AC1 (*AL1*) encodes for Replication initiation protein (Rep) (Saunders *et al.*, 2008). AC2 (*AL2*) produces Transcription activator protein (TrAP). AC3 (*AL3*) encodes for replication enhancer proteins (Tiendrebeogo *et al.*, 2008).

AC4 functions for determining symptoms expression. AV1 (*AR1*) produces Coat Protein (CP). AV2 is the movement protein also called as ("precoat" ORF). DNA B has two ORF. BV1 (*BR1*) is the producer of Nuclear shuttle protein (NSP). BC1 (*BL1*) instructs for Movement protein for cell to cell transfer (Rojas *et al.*, 2005). AV1, AV2 and BV1 are the plus (+) virion sense strand, whereas, AC1, AC2, AC3, AC4 and BC1 represents for negative (-) complementary sense strand (Yadava *et al.*, 2010). According to Fig. 2, *Curtovirus* has seven ORFs (Park *et al.*, 1999). Out of them three open reading frames (ORFs) are in the positive (virion) sense i.e., V1, V2, V3 and the rest four in the negative (complementary) sense i.e., C1, C2, C3 and C4. V1 encodes for coat protein, V2 produces

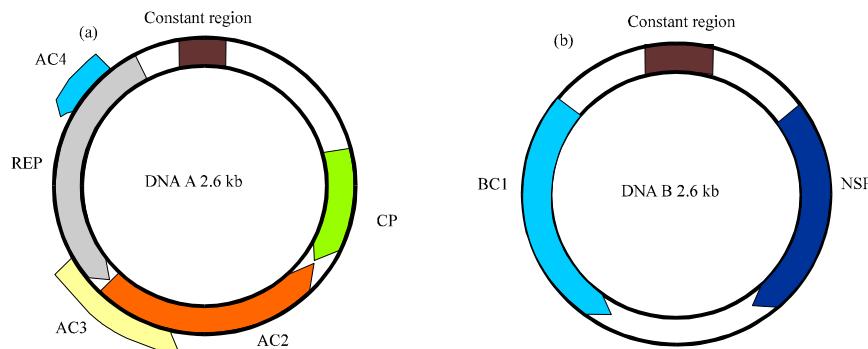

Fig. 1 (a-b): *Begomovirus* genome components, CP: Coat protein, Rep: Replication-associated protein, NSP: Nuclear shuttle protein

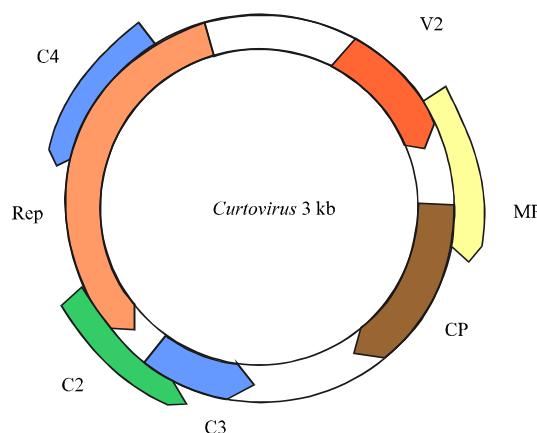

Fig. 2: *Curtovirus* genome components, CP: Coat protein, Rep: Replication-associated protein, MP: Movement protein

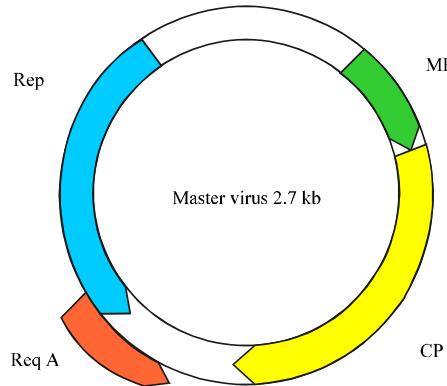

Fig. 3: *Mastrevirus* genome components, CP: Coat protein, Rep: Replication-associated protein, MP: Movement protein

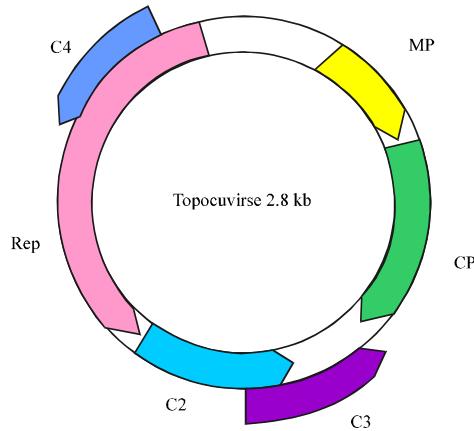

Fig. 4: *Topocuvirus* genome components, CP: Coat protein, Rep: Replication-associated protein, MP: Movement protein

an ss/dsDNA regulator, *V3* instruct for movement protein. *C1* is assigned for replication protein whereas, the *C2* has unknown function. *C3* is for the production of protein which is similar to the replication enhancer protein of *Begomovirus*. *C4* initiates cell division and for symptom determinant (Park *et al.*, 2003).

As per Fig. 3 there are four ORFs in the *Mastrevirus* genome (Boulton, 2002). Two of them on the virus (+) sense and rest two on the complementary (-) senses (Heyraud-Nitschke *et al.*, 1995). *V1* is the larger plus (+) sense ORF which encodes for the coat protein (CP) (Gutierrez *et al.*, 2004). *V2* produces Cell-to-cell movement protein (Nahid *et al.*, 2008). Complementary sense has two components, *C1* encodes for Rep A replication-associated protein having and *C1:C2* instruct for Replication-associated (Rep) protein which is expressed from ORFs *C1* and *C2* by transcript splicing (Xie *et al.*, 1999). *Topocuvirus* genome in the Fig. 4 have six ORFs. *V1* and *V2* instruct for coat protein and movement protein respectively (Varma and Malathi, 2003). Replicase A and Replicase B are respectively produced by *C1* and *C2*. *C3* encodes for replication enhancer protein having function similar to that of *Begomovirus* replication enhancer protein. Cell division is initiated by the *C4* component. *V1* and *V2* fall in the plus sense and *C1*, *C2*, *C3* comes in the negative sense region (Govindappa *et al.*, 2011).

REPLICATION: A GENERAL VIEW

Geminiviruses of the genera *Begomovirus* and *Curtovirus* utilize three replication modes: Complementary-Strand Replication (CSR), Rolling-Circle Replication (RCR) (Saunders *et al.*, 1991) and Recombination-Dependent Replication (RDR) (Alberter *et al.*, 2005). But RCR is the general mechanism common to all the four genera (Fig. 5). It is not possible for the Geminiviruses to replicate themselves (Bisaro, 1996). So, they evolve themselves by using plant cell machinery for their survival. They undergo rolling circle replication through which their DNA replicates. This process is quite similar to the infection of Bacteriophages like M13. Principally these viruses depend on host DNA Polymerases, probably repair polymerases (Chasan, 1995). Moreover, transcription factors are also the main ingredients in their multiplication.

The first step in their proceedings in the entry of the viruses in the plant cells which is carried out by their transmission vectors. Once they are inside as soon as possible their genomic DNA gets in the cell nucleus of the infected host cell to assist with viral DNA replication. Rep commences virus-specific recognition of its cognate origin (Hanley-Bowdoin *et al.*, 1999). Their single stranded circular DNA gets converted into a double stranded DNA. Their ssDNA is called as a plus or + or positive sense strand acting as a template DNA. The complementary DNA which is formed from the template DNA using DNA repair enzymes is called as a negative (-) sense strand (Kaliappan *et al.*, 2012). Now the Rep protein of the virus cleaved the viral strand at their specific origin of replication site, thus the rolling circle phase starts. Now the new single stranded DNA gets packed into the geminate particles in the nucleus and is ready for new infections (Gutierrez, 2000).

CURRENT RESEARCH ON GEMINIVIRUSES

This review article illustrates the existing status of *Geminivirus* in India. It enlightens the research being carried out on *Geminivirus* which includes their molecular, serological and computational characterization. Moreover, stating various research institute and university where works on geminiviruses are being carried out and includes a wide range of information mentioning the new disease reports from throughout India.

A variant of tomato leaf curl Bangladesh virus was found infecting *Gaillardia* (Mahatma and Mahatma, 2012). Sequence analysis using the BLAST programme revealed nucleotide sequence identities of 94.0% with Tomato leaf curl Bangladesh virus-(Bangladesh:2) (ToLCBDV-[BD:2]) (AF188481) and 92.0% with Chilli leaf curl virus-DU [India: New Delhi: Papaya: 2009 (HM140364)]. Moreover a *Begomovirus* infecting *Mentha spicata* was also reported in Lucknow and in the Tarai region of Uttaranchal province. Its sequence showed 93% identity with the *Begomovirus* Tomato leaf curl Pakistan virus (Samad *et al.*, 2009). This confirms the invasion of foreign species in India from adjacent countries.

Sunn hemp (*Crotalaria juncea*) extensively cultivated in India as a fiber or green manure crop which was found infected by an Indian tomato leaf curl virus. The CP gene of Indian tomato leaf curl virus was used as a DNA probes (IToLCV) for the identification of the disease (Khan *et al.*, 2002). *Cyamopsis tetragonoloba* (Guar), an important cultivated crop in India was found infected by Tomato leaf curl virus (ToLCV). Nucleotide sequence identity regions of the CP genes of Tomato leaf curl virus (ToLCV) of Indian isolates were carried out (Khan *et al.*, 2003). It revealed mutual

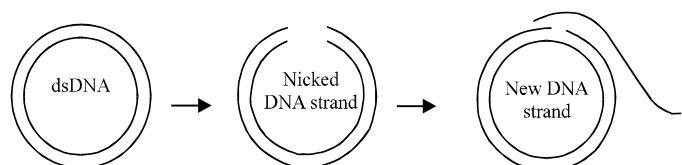

Fig. 5: Rolling circle replication

95% sequence identity with ToLCV-BanII (accession number U38239); 91% with ToLCV-BanI (accession no. Z 48182), ToLCV-BaV (accession no. AF 295401) and ToLCV-Kolar (accession no. AF 428255); 90% with ToLCV-BanIV (accession no. AF 165098). *Glycine max* (soybean) was also affected by *Begomovirus*. When analysis of nucleotide sequence was done by BLAST the search revealed that the highest nucleotide sequence identity (96-98%) comes with Tomato leaf curl Karnataka virus (ToLCKV) (TLU38239, AJ810342, AY753203, AJ810370 and AJ810347) (Raj *et al.*, 2006).

Sequence analysis of *Calendula officinalis* revealed the highest nucleotide sequence identities (95, 94 and 93%) of the virus infecting *Calendula* with Tobacco curly shoot virus (AF240675), *Ageratum* enation virus (AJ437618) and Tomato leaf curl Bangladesh virus (AF188481), respectively (Khan *et al.*, 2005). *Sechium edule* (Chayote) belongs to Cucurbitaceae vegetable family commonly grown in Darjeeling and Sikkim hills regions of India during the summer-rainy season. The maximum sequence identity (95%) was found with ToLCV-NDe from Pakistan (AF448058), but have only 70.7% identity with Chayote yellow mosaic virus (ChYMV; AJ223191), which is the uncharacterized virus, reported from Nigeria (Mandal *et al.*, 2004).

A new monopartite *Begomovirus* species, Chilli leaf curl Vellanad virus and associated betasatellites was found infecting chilli in the Vellanad region of Kerala, India. It was fully sequenced and revealed a viral genome (HM007121) of 2,788 nt consisting of seven predicted ORFs (AV1, AV2, AC1, AC2, AC3, AC4, AC5). Sequence alignment was done using MegAlign (DNASTAR, Madison, WI) and demonstrated that the virus had the highest levels of nucleotide sequence identity (77%) with a 'Pakistan' strain of Pepper leaf curl Bangladesh virus (AF314531) (Kumar *et al.*, 2012b). *Clerodendrum inerme* belongs to family Verbenaceae and it is a common hedge type plant used to grow in gardens. 80% nucleotide sequence identity matches with the Cotton leaf curl kokhran virus (AY456683). Less than 78% identity were detected against ToLCNDV (John *et al.*, 2006).

Leaf curl disease in potato (*Solanum tuberosum*) was found to be caused by a strain of Tomato leaf curl New Delhi virus (ToLCNDV). It had 93-95% sequence identity with the DNA A of ToLCNDV and have less than 75% identity with other Tomato leaf curl virus isolates and Potato yellow mosaic virus (Usharani *et al.*, 2004). *Begomovirus* affecting *Gossypium barbadense* depicted 84-85% nucleotide sequence identity of its DNA A with the Cotton leaf curl Multan virus (CLCuMV, AJ002447, AJ002459), followed by 83.4% with Malvastrum yellow vein virus (MYVV, AJ457824). On the other hand conserved C1 gene of the DNA-B showed highest nucleotide identities about 89.1-89.6% and amino acid sequence identity of about 80.5-81.4% with similar sequences from tomato (AJ316035) and *G. hirsutum* (AJ298903) reported from Pakistan (Reddy *et al.*, 2005).

Radish leaf curl virus was found infecting okra in Bihar state of India. For virus and satellite transmission from field-collected infected plants to healthy tobacco and okra, Healthy whiteflies (~25) were used for infectivity assay. Tobacco and okra (10 plants each) was inoculated with a mixture of *Begomovirus* and alpha- and betasatellite infectious clones. Plants of both assays yielded typical symptoms of leaf curling and stunting identical to those observed previously in the field (Kumar *et al.*, 2012a). A *Begomovirus* caused Indian dolichos yellow mosaic disease in Dolichos (*Lablab purpureus*) which is a popular leguminous vegetable cultivated in India. It had 95.3 and 93.4% nucleotide sequence identity with DoYMV-[Bangladesh] (AY271891) and DoYMV originating from India (AY309241), respectively (Maruthi *et al.*, 2006). *Capsicum annuum* (Chilli) is cultivated throughout India as an important spice crop. The plant was found affected by Chilli leaf curl virus. It demonstrate closed similarity of its replication initiator protein, AV1 and AV2 genes of Chilli leaf curl virus-[Pakistan: Multan] (ChiLCuV-[Pk:Mul]; AF336806) (Senanayake *et al.*, 2007).

In another report Chilli was also affected by Tomato leaf curl New Delhi virus (ToLCNDV). It showed 89-93% identity with various ToLCNDV viruses like X78956, AY428769, TLU15016 and AF448058 (Khan *et al.*, 2005). *Vigna unguiculata* (Cowpea) were infected by Mungbean yellow mosaic India virus. The nucleotide sequence of its DNA β has shown 59% identity with DNA β of Cotton leaf curl Rajasthan virus (Accession No. AY083590) (Rouhibakhsh and Malathi, 2005). Tomato leaf curl Joydebpur virus was found infecting *Capsicum annuum*. The chilli *Begomovirus* genome organization from Punjab shows 90.8 and 90.3% sequence identity to that of tomato *Begomovirus* from India (DQ629103) and tomato leaf curl Joydebpur virus (ToLCJV, AJ875159), respectively (Shih *et al.*, 2007). A bipartite *Begomovirus* affecting tomato in India was found. The study demonstrates the role of a betasatellite in the pathogenesis of tomato leaf curl New Delhi virus (ToLCNDV). For infection, DNA A alone of ToLCNDV could infect tomato and *Nicotiana benthamiana* and induce mild symptoms, but DNA B or Cotton leaf curl Multan betasatellite (CLCuMB) was required for development of typical leaf curl symptoms (Sivalingam and Varma, 2012).

Yellow vein mosaic disease was found infecting *Abelmoschus esculentus* L., New Delhi, India. DNA-A and DNA-B was completely sequenced and were comprised of 2,746 and 2,703 nucleotides, respectively. The betasatellite (DNA- β) component was absent in the sample (Venkataravanappa *et al.*, 2012). Comparison of DNA-A component with other known begomoviruses showed 85.9% similarity with bhendi yellow vein mosaic Delhi virus [BYVDV-IN (India: Delhi: Okra)]. DNA-B showed highest sequence identity (87.8% identical) to that of a ToLCNDV (AY158080). *Cajanus cajan* (Pigeonpea) belongs to family Fabaceae is affected by *Begomovirus* (Acc. No. AY927997). When compared it confirmed highest nucleotide sequence identities of about 95-97% with ToLCNDV-Mild (U15016); ToLCNDV-[Lucknow] (Y16421); ToLCNDV-[Solanum] (AJ620187); a ToLCNDV isolated from Luffa (AY309957); *Cucurbita maxima* yellow mosaic virus (AY396151) and Pumpkin yellow vein mosaic virus (AY184487) (Raj *et al.*, 2005). *Hibiscus cannabinus* (Kenaf) belongs to family Malvaceae grown as a fiber crop in India. Its PCR was done by using forward and reverse primers. The forward primer has sequence 5'-CAGAACCCCTGATGTTCCAAG-3' and the reverse primer has sequence 5'-TACATCCTGTACAGTCTGGC-3' which was used against the coat protein gene of the *Begomovirus* (EU366903) (Paul *et al.*, 2009). The *Begomovirus* and betasatellite showed the highest levels of sequence identity (95 and 92%, respectively) with tomato leaf curl Joydebpur virus (ToLCJV, AJ875159) and its associated betasatellite (ToLCJB, AJ966244) reported from Bangladesh.

Cloning and sequencing were done to partially characterize the *Begomovirus* infecting *Sida cordifolia* L., *Croton bonplandianum* L., *Malachra capitata* L., *Eclipta prostrata* L., *Clerodendrum inerme* L., *Acalypha indica* L. and *Urena lobata* L. which are common weeds found all over India. In this study Coat Protein (CP) genes were found to be amplified from all the infected samples tested, whereas betasatellite molecules amplified only from four infected samples (Sida, Croton, Malachra and Urena). Their genetic pattern was compared with respective geographical isolates throughout India (Paul *et al.*, 2012). Jute (*Corchorus capsularis*) one of the largest fiber crops cultivated in India. It belongs to the family Tiliaceae. Found to be infected by *Begomovirus* (EU047706) showing Yellow mosaic disease. BLAST analysis revealed that it showed 91.2% similarity in its nucleotide sequence with Corchorus golden mosaic virus (DQ641688) (Ghosh *et al.*, 2008). *Begomovirus* (EU439259) affecting *Amaranthus cruentus* (Grain amaranth) and causing yellow vein net disease has shown 98% sequence identity with Ageratum Enation Virus (AEV) isolates (AJ437618) (Raj *et al.*, 2008). Current research on Geminiviruses (Fig. 6) are carried out at various places in renowned research institutions in India.

Two research projects are going at Mody Institute of Technology and Science (MITS), Lakshmangarh, Rajasthan entitled 'RNAi mediated resistance against *Begomovirus*' (DBT funded Project No. BT/PR13129/ GBD/27/197/2009) and "Coordinate approach to creating Transgenic Cotton resistant against Begomoviruses" (DST project no. SR/FT/LS-o42/2009). Around 53 various *Begomovirus* sequences were submitted in NCBI. Their various Genebank Accession Numbers are as follows: HQ631429-HQ631431, JN000700-JN000703, NC-015631, JF968443, JF968444, JN009664-JN009667, HQ876467, JN998441-JN998453, JQ407224, JQ693136-JQ693151. The submitted sequences are of *Begomovirus* infecting ornamental plants such as *Alternanthera sessilis*, *Clerodendrum inerme*, *Calendula officinalis* etc. (Fig. 7) and also include some weeds and crops plants such as *Sonchus asper*, *Datura inoxia*, *Capsicum* sp. etc. (Fig. 8).

Research on *Geminivirus* Recombination (Marwal *et al.*, 2012a), Homology modeling and docking studies are also being carried out on ornamental plants, weeds and crops (Prajapat *et al.*, 2011). A number of first disease reports have also been discovered such as *Begomovirus* infecting *Datura inoxia*, *Mimosa pudica* (Gaur *et al.*, 2011; Marwal *et al.*, 2012b).

Fig. 7(a-b): *Begomovirus* symptoms of (a) Leaf curl disease in *Alternanthera sessilis* and (b) Mosaic symptoms on *Clerodendrum inerme*

Fig. 8(a-b): *Begomovirus* symptoms of (a) Vein yellowing and mosaic on *Sonchus asper* and (b) Leaf curl disease in *Capsicum* species

Geminivirus Database (GVDB) has also been developed at MITS. The objective of the *Geminivirus* Database (GVDB) was to design and provide tool for genetic and *In silico* analysis of *Geminivirus* and its genera *Begomovirus*. It provides a platform for the current status and research on *Geminivirus* especially with reference to *Begomovirus* infection in different plants across India. The GVDB comprises of partial and complete nucleotide sequences of weed, ornamentals etc infecting begomoviruses. Homology modeling and docking results of different begomoviral proteins (cds) were also enclosed. Homology modeling is a bright field to understand and study the genetic diversity of begomoviruses. It involves the prediction of various proteins and helpful to biologist to develop resistance against various *Geminivirus*s (Prajapat *et al.*, 2010).

This database is endowed with comprehensive information about *Geminivirus* members that grounds infection in various plants species in India assorting from ornamentals plants to common weeds and other plants. The home page of this database offers various links associated with current research programmes, future proposed direction of *Geminivirus* research. The programming and platform of GVDB was developed by perfect Info desk Pvt. Ltd., Jaipur, Rajasthan (India). Domain name www.wikiGeminivirus.org (domain id: D161538660-LROR) was registered at server ns195.ehostpros.com and developed by using online applications of Joomla because it is an open source Content of Management System (CMS). Results of research were used for the designing on MySQL 4.1 (www.mysql.com) by using PHP 5.2 (Hypertext Preprocessor, www.php.net) as front end and the computing platform on Linux.

DIVERSITY AMONG INDIAN *Geminivirus*

India has a vast diversity of *Geminivirus*s. Some infections are from Indian origin and some comes across the border from the adjacent countries such as Pakistan, Sri Lanka, Bangladesh and other adjacent countries. Table 1 shows almost all the reported *Geminivirus*s across India (Fauquet *et al.*, 2008).

Table 1: List of reported *Geminivirus*s in India

Species/virus name	Accession number	Abbreviation
<i>Begomovirus</i>		
Bhendi yellow vein mosaic virus (Okra yellow vein mosaic virus)

Geminiviruses causes a variety of symptoms and exhibits high rate of recombination and pseudo-recombination that contributes in the evolution of new virus strains/species (Pita *et al.*, 2001). Inter-specific recombination has resulted in remarkable diversity among Geminiviruses (Garrido-Ramirez *et al.*, 2000) and that is the major cause of the emergence of new *Geminivirus* diseases in tropical and subtropical regions. In some cases, the recombinants exhibited a new pathogenic phenotype which is often more virulent than the parents, many research reports have demonstrated evidence of recombination in a wide range of Geminiviridae genera (Marwal *et al.*, 2012a).

RNAi TECHNOLOGY: RAY OF HOPE

RNAi-mediated virus resistance was first reported against Potato virus Y (PVY) in transgenic tobacco plant (Waterhouse *et al.*, 1998). RNAi technology was used as an antiviral approach against human cell lines (Novina *et al.*, 2002) but it can be used for developing resistance against plant viruses (Waterhouse *et al.*, 2001). RNAi technology when used against a *Geminivirus* (African cassava mosaic virus (ACMV)) showed 99% decrease of Rep transcripts and 66% reduction in viral DNA. Here in it the siRNA were transiently transferred into the protoplast making it effective against the replicase (Rep)-coding sequence of the ACMV (Vanitharani *et al.*, 2003).

In view of the fact that the unearthing of RNAi in *Caenorhabditis elegans* which provide as an experiment archetypical and its study in *Drosophila melanogaster* and other organisms, scores of mechanism for RNA interference has been recommended (Montgomery *et al.*, 1998). RNA interference is a phenomenon primarily for the regulation of gene expression; self or non self depending upon the surrounding factors or conditions, with the help of RNA molecules that are non coding in nature to control cellular metabolism or simply called post transcriptional gene silencing (Dhakar *et al.*, 2010; Chang *et al.*, 2012). Short interfering RNAs (siRNAs), the 21-to 28-nt double-stranded intermediates of this natural defense mechanism, are becoming powerful tools for reducing gene expression and countering viral infection in a variety of cells (Rougemaille *et al.*, 2012).

The DICER complex which is RNAse III like enzymes (Bernstein *et al.*, 2001) responsible for RNAi pathway exists in two forms: Dcr-1/Loquacious (Loqs)-PB (also known as R3D1-L[long]): generate miRNA and Dcr-2/R2D2 generates siRNA. Dcr-1 is an enzyme that shows ATP independent functions (Lee *et al.*, 2004) and affinity towards stem-loop form of RNA (precursor of miRNA). Dcr-2 shows ATP dependent activity with substrate specificity to double stranded RNA. R2D2 contains 2 ds RNA binding domains (ds RBDs). Dcr2/r2d2 heterodimer binds to siRNA forms RDI complex (R2D2 Dcr Initiator complex) and helps it to load into RNA silencing effector complex such as RNA-induced silencing complex called as RISC (Hammond *et al.*, 2000) by forming (RLC) RISC Loading Complex. RLC then recruits and associates with Ago 2 protein forming holo-RISC from Pre-RISC after the removal of passenger strand (Van Mierlo *et al.*, 2012).

The holo-RISC then acts as the effective machinery for gene silencing. As the guide strand of RISC binds with the corresponding mRNA, the endonuclease activity of the complex degrades the mRNA thereby resulting in Post Transcriptional Gene Silencing (PTGS) (Liu *et al.*, 2012). RNA interference silencing mechanism could amplify its signal intensity, termed as Transitivity. A role of RNA dependent RNA polymerase (RdRP) was assumed in this mechanism (Zhang *et al.*, 2012). Two models were proposed: (1) RdRP generates the newly synthesized siRNA directly (2) RdRP use siRNA as a template for the production of long dsRNA, which are then cleaved into siRNA. Mobility of the silencing signal termed as system is spread by specific proteins moving across plasmodesmata in phloem thus activating RNAi (Himber *et al.*, 2003).

Targeting Rep and AV₂ gene by antisense technology is found to be quite successful (Sanjaya *et al.*, 2005). To make PTGS an effective method both sense and antisense RNAs is a prerequisite and a transgenic tobacco (*Nicotiana benthamiana*) using RNAi was developed (Dasgupta *et al.*, 2003). Using RNA silencing approach AC2 protein of mungbean yellow mosaic India virus (MYMIV) was effectively suppressed (Singh *et al.*, 2007). Reduction in rep mRNA of MYMIV was achieved by the catalytic activity of both active and inactive ribozyme which is primarily due to the of Rep-siRNAs formation in presence of the ribozymes (Chilakamarthi *et al.*, 2007).

The hairpin construct of coat protein made, has 35 S promoter (1.3 kb), sense sequence of MYMIV (130 bp) followed by intron (741 bp), after which the antisense (130 bp) target sequence and OCS terminator (765 bp) were cloned in cloning vector pHANNIBAL. Results indicated that, co-agro inoculation of coat protein hairpin construct (Cphp) prevent viral pathogenesis (Kumari and Malathi, 2012). Success has also achieved in developing resistance against AC1 and AC4 viral genes of tomato leaf curl virus. Moreover transgenic lines of popular potato cultivars Kufri Badshah and Kufri Pukhraj with increased potato apical leaf curl virus (PALCV) resistance using RNAi technology targeting the replication associated protein gene (AC1) of the virus were also developed (Tomar *et al.*, 2012). Strategies like Intron-spliced hairpin RNAs, small hairpin RNAs, self-complementary inverted repeats and antisense technology were used to developed resistance (Ramesh *et al.*, 2007). Transgenic resistance against begomoviruses has been achieved in a number of plants using a variety of strategies. The results presented above showed that the RNAi approach has been investigated extensive which is a powerful tool for biochemical studies for developing transgenic plants and a ray of hope for various challenging geminiviral diseases.

CONCLUSION AND FUTURE PROSPECTS

India is an agriculture based country. A wide variety of plants species are grown in India such as economically important crops and ornamentals plants. Indian weather is tropical in nature and is very much suitable for the prevalence of white fly which is the main vector for causing *geminiviral* infections. Due to which a number of new viral species have being found in India, includes a wide range of information mentioning the new disease reports from throughout India. Indian *Begomovirus* have a diverse kind of host range for example tomato leaf curl virus was found infecting *Crotalaria juncea*, *Solanum tuberosum* and *Cyamopsis tetragonoloba*. Similarly radish leaf curl virus was found infecting okra.

There are also reports which enlightens the prevalence of *Begomovirus* from neighboring countries such as Pakistan, Sri Lanka, Bangladesh etc for example tomato leaf curl Bangladesh virus was found infecting *Gaillardia*, tomato leaf curl Pakistan virus was found infecting *Mentha spicata*. An expected consequence of this scenario would be recombination which plays an important role for the evolution of new *Geminivirus* strains in India and these new strains are responsible for heavy loss of new host variety. Thus there is an urgent need of controlling *Begomovirus* infections. The use of computational and molecular techniques e.g., RNAi is a potential tools for reducing the prevalence of various *Geminivirus* diseases. Results of these techniques effectively applied for disease management, crop protection and development of quarantine strategies at state and national level in India.

ACKNOWLEDGMENTS

The authors would like to acknowledge a vote of thanks to Department of Biotechnology (DBT project No. BT/PR13129/GBD/27/197/2009) and Department of Science and Technology (DST project no. SR/FT/LS-042/2009), India for their financial support.
